SWI-Prolog 5.6
Reference Manual

Updated for version 5.6.59, August 2008

Jan Wielemaker
wielemak@science.uva.nl
http://www.swi-prolog.org

SWI-Prolog is a Prolog implementation based on a subset of the WAM (Warren Abstract Machine). SWI-Prolog was developed as an open Prolog environment, providing a powerful and bi-directional interface to C in an era this was unknown to other Prolog implementations. This environment is required to deal with XPCE, an object-oriented GUI system developed at SWI. XPCE is used at SWI for the development of knowledge-intensive graphical applications.

As SWI-Prolog became more popular, a large user-community provided requirements that guided its development. Compatibility, portability, scalability, stability and providing a powerful development environment have been the most important requirements. Edinburgh, Quintus, SICStus and the ISO-standard guide the development of the SWI-Prolog primitives.

This document gives an overview of the features, system limits and built-in predicates.

Introduction

1.1 SWI-Prolog

SWI-Prolog started back in 1986 with the requirement for a Prolog that could handle recursive interaction with the C-language: Prolog calling C and C calling Prolog recursively. Those days Prolog systems were very aware of its environment and we needed such a system to support interactive applications. Since then, SWI-Prolog’s development has been guided by requests from the user community, especially focussing on (in arbitrary order) interaction with the environment, scalability, (I/O) performance, standard compliance, teaching and the program development environment.

SWI-Prolog is based on a very simple Prolog virtual machine called ZIP [Bowen et al., 1983, Neumerkel, 1993] which defines only 7 instructions. Prolog can easily be compiled into this language and the abstract machine code is easily decompiled back into Prolog. As it is also possible to wire a standard 4-port debugger in the virtual machine there is no need for a distinction between compiled and interpreted code. Besides simplifying the design of the Prolog system itself this approach has advantages for program development: the compiler is simple and fast, the user does not have to decide in advance whether debugging is required and the system only runs slightly slower when in debug mode. The price we have to pay is some performance degradation (taking out the debugger from the VM interpreter improves performance by about 20%) and somewhat additional memory usage to help the decompiler and debugger.

SWI-Prolog extends the minimal set of instructions described in [Bowen et al., 1983] to improve performance. While extending this set care has been taken to maintain the advantages of decompilation and tracing of compiled code. The extensions include specialised instructions for unification, predicate invocation, some frequently used built-in predicates, arithmetic, and control (;/2, 1;/2), if-then (->/2) and negation-by-failure (\+/1).

1.1.1 Books about Prolog

This manual does not describe the full syntax and semantics of Prolog, nor how one should write a program in Prolog. These subjects have been described extensively in the literature. See [Bratko, 1986], [Sterling & Shapiro, 1986], and [Clocksin & Melish, 1987]. For more advanced Prolog material see [O’Keefe, 1990]. Syntax and standard operator declarations confirm to the ‘Edinburgh standard’. Most built in predicates are compatible with those described in [Clocksin & Melish, 1987]. SWI-Prolog also offers a number of primitive predicates compatible with Quintus Prolog⁠¹ [Qui, 1997] and BIM_Prolog² [BIM, 1989].

ISO compliant predicates are based on “Prolog: The Standard”, [Deransart et al., 1996], validated using [Hodgson, 1998].

⁠¹Quintus is a trademark of Quintus Computer Systems Inc., USA
⁠²BIM is a trademark of BIM sa/nv., Belgium
1.2 Status

This manual describes version 5.6 of SWI-Prolog. SWI-Prolog has been used now for many years. The application range includes Prolog course material, meta-interpreters, simulation of parallel Prolog, learning systems, natural language processing, complex interactive systems, web-server and web-server components. Although in our experience rather obvious and critical bugs can remain unnoticed for a remarkable long period, we assume the basic Prolog system is fairly stable. Bugs can be expected in infrequently used built-in predicates.

Some bugs are known to the author. They are described as footnotes in this manual.

1.3 Compliance to the ISO standard

SWI-Prolog 3.3.0 implements all predicates described in “Prolog: The Standard” [Deransart et al., 1996].

Exceptions and warning are still weak. Some SWI-Prolog predicates silently fail on conditions where the ISO specification requires an exception (functor/3 for example). Some predicates print warnings rather than raising an exception. All predicates where exceptions may be caused due to a correct program operating in an imperfect world (I/O, arithmetic, resource overflows) should behave according to the ISO standard. In other words: SWI-Prolog should be able to execute any program conforming to [Deransart et al., 1996] that does not rely on exceptions generated by errors in the program.

1.4 Should you be using SWI-Prolog?

There are a number of reasons why you better choose a commercial Prolog system, or another academic product:

- **SWI-Prolog is not supported**
  Although I usually fix bugs shortly after a bug report arrives, I cannot promise anything. Now that the sources are provided, you can always dig into them yourself.

- **Memory requirements and performance are your first concerns**
  A number of commercial compilers are more keen on memory and performance than SWI-Prolog. I do not wish to sacrifice some of the nice features of the system, nor its portability to compete on raw performance.

- **You need features not offered by SWI-Prolog**
  In this case you may wish to give me suggestions for extensions. If you have great plans, please contact me (you might have to implement them yourself however).

On the other hand, SWI-Prolog offers some nice facilities:

- **Nice environment**
  This includes ‘Do What I Mean’, automatic completion of atom names, history mechanism and a tracer that operates on single key-strokes. Interfaces to some standard editors are provided (and can be extended), as well as a facility to maintain programs (see make/0).
• **Very fast compiler**
  Even very large applications can be loaded in seconds on most machines. If this is not enough, there is a Quick Load Format that is slightly more compact and loading is almost always I/O bound.

• **Transparent compiled code**
  SWI-Prolog compiled code can be treated just as interpreted code: you can list it, trace it, etc. This implies you do not have to decide beforehand whether a module should be loaded for debugging or not. Also, performance is much better than the performance of most interpreters.

• **Profiling**
  SWI-Prolog offers tools for performance analysis, which can be very useful to optimise programs. Unless you are very familiar with Prolog and Prolog performance considerations this might be more helpful than a better compiler without these facilities.

• **Flexibility**
  SWI-Prolog can easily be integrated with C, supporting non-determinism in Prolog calling C as well as C calling Prolog (see section 9). It can also be **embedded** in external programs (see section 9.7). System predicates can be redefined locally to provide compatibility with other Prolog systems.

• **Integration with XPCE**
  SWI-Prolog offers a tight integration to the Object Oriented Package for User Interface Development, called XPCE [Anjewierden & Wielemaker, 1989]. XPCE allows you to implement graphical user interfaces that are source-code compatible over Unix/X11, Win32 (Windows 95/98/ME and NT/2000/XP) and MacOS X (darwin).

### 1.5 The XPCE GUI system for Prolog

The XPCE GUI system for dynamically typed languages has been with SWI-Prolog for a long time. It is developed by Anjo Anjewierden and Jan Wielemaker from the department of SWI, University of Amsterdam. It aims at a high-productive development environment for graphical applications based on Prolog.

Object oriented technology has proven to be a suitable model for implementing GUIs, which typically deal with things Prolog is not very good at: event-driven control and global state. With XPCE, we designed a system that has similar characteristics that make Prolog such a powerful tool: dynamic typing, meta-programming and dynamic modification of the running system.

XPCE is an object-system written in the C-language. It provides for the implementation of methods in multiple languages. New XPCE classes may be defined from Prolog using a simple, natural syntax. The body of the method is executed by Prolog itself, providing a natural interface between the two systems. Below is a very simple class definition.

```prolog
:- pce_begin_class(prolog_lister, frame,
   "List Prolog predicates").

initialise(Self) :->
   "As the C++ constructor":
   send_super(Self, initialise, 'Prolog Lister'),
```

1.6 RELEASE NOTES

```
send(Self, append, new(D, dialog)),
send(D, append,
    text_item(predicate, message(Self, list, @arg1))),
send(new(view), below, D).
```

```
list(Self, From:name) :-
    "List predicates from specification"::
    (    catch(term_to_atom(Term, From), _, fail)
    -> get(Self, member, view, V),
        current_output(Old),
        pce_open(V, write, Fd),
        set_output(Fd),
        listing(Term),
        close(Fd),
        set_output(Old)
    ;    send(Self, report, error, 'Syntax error')
    ).
```

```
:- pce_end_class.
```

```
test : - send(new(prolog_lister), open).
```

Its 165 built-in classes deal with the meta-environment, data-representation and—of course—
graphics. The graphics classes concentrate on direct-manipulation of diagrammatic representations.

**Availability.** XPCE runs on most Unix\textsuperscript{tm} platforms, Windows 95/98/ME, Windows NT/2000/XP and MacOS X (using X11). In the past, versions for Quintus- and SICStus Prolog as well as some Lisp dialects have existed. After discontinuing active Lisp development at SWI the Lisp versions have died. Active development on the Quintus and SICStus versions has been stopped due to lack of standardisation in the Prolog community. If adequate standards emerge we are happy to actively support other Prolog implementations.

**Info.** further information is available from http://www.swi-prolog.org/packages/xpce/ or by E-mail to info@www.swi-prolog.org.

## 1.6 Release Notes

Collected release-notes. This section only contains some highlights. Smaller changes to especially older releases have been removed. For a complete log, see the file ChangeLog from the distribution.

### 1.6.1 Version 1.8 Release Notes

Version 1.8 offers a stack-shifter to provide dynamically expanding stacks on machines that do not offer operating-system support for implementing dynamic stacks.
1.6.2 Version 1.9 Release Notes

Version 1.9 offers better portability including an MS-Windows 3.1 version. Changes to the Prolog system include:

- **Redefinition of system predicates**
  Redefinition of system predicates was allowed silently in older versions. Version 1.9 only allows it if the new definition is headed by a `:- redefine_system_predicate/1` directive.

- **‘Answer’ reuse**
  The top-level maintains a table of bindings returned by top-level goals and allows for reuse of these bindings by prefixing the variables with the $ sign. See section 2.8.

- **Better source code administration**
  Allows for proper updating of multifile predicates and finding the sources of individual clauses.

1.6.3 Version 2.0 Release Notes

New features offered:

- **32-bit Virtual Machine**
  Removes various limits and improves performance.

- **Inline foreign functions**
  ‘Simple’ foreign predicates no longer build a Prolog stack-frame, but are directly called from the VM. Notably provides a speedup for the test predicates such as `var/1`, etc.

- **Various compatibility improvements**

- **Stream based I/O library**
  All SWI-Prolog’s I/O is now handled by the stream-package defined in the foreign include file `SWI-Stream.h`. Physical I/O of Prolog streams may be redefined through the foreign language interface, facilitating much simpler integration in window environments.

1.6.4 Version 2.5 Release Notes

Version 2.5 is an intermediate release on the path from 2.1 to 3.0. All changes are to the foreign-language interface, both to user- and system-predicates implemented in the C-language. The aim is twofold. First of all to make garbage-collection and stack-expansion (stack-shifts) possible while foreign code is active without the C-programmer having to worry about locking and unlocking C-variables pointing to Prolog terms. The new approach is closely compatible to the Quintus and SIC-Stus Prolog foreign interface using the `+term` argument specification (see their respective manuals). This allows for writing foreign interfaces that are easily portable over these three Prolog platforms.

Apart from various bug fixes listed in the ChangeLog file, these are the main changes since 2.1.0:

- **ISO compatibility**
  Many ISO compatibility features have been added: open/4, arithmetic functions, syntax, etc.
1.6. RELEASE NOTES

- **Win32**
  Many fixes for the Win32 (NT, ’95 and win32s) platforms. Notably many problems related to
  pathnames and a problem in the garbage collector.

- **Performance**
  Many changes to the clause indexing system: added hash-tables, lazy computation of the index
  information, etc.

- **Portable saved-states**
  The predicate `qsave_program/[1,2]` allows for the creating of machine independent
  saved-states that load very quickly.

1.6.5 Version 2.6 Release Notes

Version 2.6 provides a stable implementation of the features added in the 2.5.x releases, but at the
same time implements a number of new features that may have impact on the system stability.

- **32-bit integer and double float arithmetic**
  The biggest change is the support for full 32-bit signed integers and raw machine-format double
  precision floats. The internal data representation as well as the arithmetic instruction set and
  interface to the arithmetic functions has been changed for this.

- **Embedding for Win32 applications**
  The Win32 version has been reorganised. The Prolog kernel is now implemented as Win32 DLL
  that may be embedded in C-applications. Two front ends are provided, one for window-based
  operation and one to run as a Win32 console application.

- **Creating stand-alone executables**
  Version 2.6.0 can create stand-alone executables by attaching the saved-state to the emulator.
  See `qsave_program/2`.

1.6.6 Version 2.7 Release Notes

Version 2.7 reorganises the entire data-representation of the Prolog data itself. The aim is to remove
most of the assumption on the machine’s memory layout to improve portability in general and enable
embedding on systems where the memory layout may depend on invocation or on how the executable
is linked. The latter is notably a problem on the Win32 platforms. Porting to 64-bit architectures is
feasible now.

Furthermore, 2.7 lifts the limits on arity of predicates and number of variables in a clause consid-
erably and allow for further expansion at minimal cost.

1.6.7 Version 2.8 Release Notes

With version 2.8, we declare the data-representation changes of 2.7.x stable. Version 2.8 exploits the
changes of 2.7 to support 64-bit processors like the DEC Alpha. As of version 2.8.5, the representation
of recorded terms has changed, and terms on the heap are now represented in a compiled format.
SWI-Prolog no longer limits the use of malloc() or uses assumptions on the addresses returned by this
function.
1.6.8 Version 2.9 Release Notes

Version 2.9 is the next step towards version 3.0, improving ISO compliance and introducing ISO compliant exception handling. New are catch/3, throw/1, abolish/1, write_term/1, write_canonical/1, and the C-functions PL_exception() and PL_throw(). The predicates display/[1,2] and displayq/[1,2] have been moved to backcomp, so old code referring to them will autoload them.

The interface to PL_open_query() has changed. The debug argument is replaced by a bitwise or'ed flags argument. The values FALSE and TRUE have their familiar meaning, making old code using these constants compatible. Non-zero values other than TRUE (1) will be interpreted different.

1.6.9 Version 3.0 Release Notes

Complete redesign of the saved-state mechanism, providing the possibility of ‘program resources’. See resource/3, open_resource/3, and qsave_program/[1,2].

1.6.10 Version 3.1 Release Notes

Improvements on exception-handling. Allows relating software interrupts (signals) to exceptions, handling signals in Prolog and C (see on_signal/3 and PL_signal()). Prolog stack overflows now raise the resource_error exception and thus can be handled in Prolog using catch/3.

1.6.11 Version 3.3 Release Notes

Version 3.3 is a major release, changing many things internally and externally. The highlights are a complete redesign of the high-level I/O system, which is now based on explicit streams rather than current input/output. The old Edinburgh predicates (see/1, tell/1, etc.) are now defined on top of this layer instead of the other way around. This fixes various internal problems and removes Prolog limits on the number of streams.

Much progress has been made to improve ISO compliance: handling strings as lists of one-character atoms is now supported (next to character codes as integers). Many more exceptions have been added and printing of exceptions and messages is rationalised using Quintus and SICStus Prolog compatible print_message/2, message_hook/3 and print_message_lines/3. All predicates described in [Deransart et al., 1996] are now implemented.

As of version 3.3, SWI-Prolog adheres the ISO logical update view for dynamic predicates. See section 4.13.1 for details.

SWI-Prolog 3.3 includes garbage collection on atoms, removing the last serious memory leak especially in text-manipulation applications. See section 9.6.2. In addition, both the user-level and foreign interface supports atoms holding 0-bytes.

Finally, an alpha version of a multi-threaded SWI-Prolog for Linux is added. This version is still much slower than the single-threaded version due to frequent access to ‘thread-local-data’ as well as some too detailed mutex locks. The basic thread API is ready for serious use and testing however. See section 8.

Incompatible changes

A number of incompatible changes result from this upgrade. They are all easily fixed however.
• !/0, call/1
  The cut now behaves according to the ISO standard. This implies it works in compound goals
  passed to call/1 and is local to the condition part of if-then-else as well as the argument of
  \
  \+/1.

• atom_chars/2
  This predicate is now ISO compliant and thus generates a list of one-character atoms. The
  behaviour of the old predicate is available in the —also ISO compliant— atom_codes/2
  predicate. Safest repair is a replacement of all atom_chars into atom_codes. If you do not
  want to change any source-code, you might want to use

  user:goal_expansion(atom_chars(A,B), atom_codes(A,B)).

• number_chars/2
  Same applies for number_chars/2 and number_codes/2.

• feature/2, set_feature/2
  These are replaced by the ISO compliant current_prolog_flag/2 and
  set_prolog_flag/2. The library backcomp provides definitions for these predicates, so
  no source must be updated.

• Accessing command-line arguments
  This used to be provided by the undocumented $argv/1 and Quintus compatible library
  unix/1. Now there is also documented current_prolog_flag(argv, Argv).

• dup_stream/2
  Has been deleted. New stream-aliases can deal with most of the problems for which
  dup_stream/2 was designed and dup/2 from the clib package can with most others.

• op/3
  Operators are now local to modules. This implies any modification of the operator-table does
  not influence other modules. This is consistent with the proposed ISO behaviour and a necessity
  to have any usable handling of operators in a multi-threaded environment.

• set_prolog_flag(character_escapes, Bool)
  This Prolog flag is now an interface to changing attributes on the current source-module, effec-
  tively making this flag module-local as well. This is required for consistent handling of sources
  written with ISO (obligatory) character-escape sequences together with old Edinburgh code.

• current_stream/3 and stream_position
  These predicates have been moved to quintus.

1.6.12  Version 3.4 Release Notes

The 3.4 release is a consolidation release. It consolidates the improvements and standard conformance
of the 3.3 releases. This version is closely compatible with the 3.3 version except for one important change:
Argument order in select/3

The list-processing predicate select/3 somehow got into a very early version of SWI-Prolog with the wrong argument order. This has been fixed in 3.4.0. The correct order is select(?Elem, ?List, ?Rest).

As select/3 has no error conditions, runtime checking cannot be done. To simplify debugging, the library module checkselect will print references to select/3 in your source code and install a version of select that enters the debugger if select is called and the second argument is not a list.

This library can be loaded explicitly or by calling check_old_select/0.

1.6.13 Version 4.0 Release Notes

As of version 4.0 the standard distribution of SWI-Prolog is bundled with a number of its popular extension packages, among which the now open source XPCE GUI toolkit (see section 1.5). No significant changes have been made to the basic SWI-Prolog engine.

Some useful tricks in the integrated environment:

- Register the GUI tracer
  Using a call to guitracer/0, hooks are installed that replace the normal command-line driven tracer with a graphical front-end.

- Register PceEmacs for editing files
  From your initialisation file, you can load emacs/swi_prolog that cause edit/1 to use the built-in PceEmacs editor.

1.6.14 Version 5.0 Release Notes

Version 5.0 marks a breakpoint in the philosophy, where SWI-Prolog moves from a dual GPL/proprietary to a uniform LGPL (Lesser GNU Public Licence) schema, providing a widely usable Free Source Prolog implementation.

On the technical site the development environment, consisting of source-level debugger, integrated editor and various analysis and navigation tools progress steadily towards a mature set of tools.

Many portability issues have been improved, including a port to MacOS X (Darwin).

For details, please visit the new website at http://www.swi-prolog.org

1.6.15 Version 5.1 Release Notes

Version 5.1 is a beta-serie introducing portable multi-threading. See chapter 8. In addition it introduces many new facilities to support server applications, such as the new rlimit library to limit system resources and the possibility to set timeouts on input streams.

1.6.16 Version 5.2 Release Notes

Version 5.2 consolidates the 5.1.x beta series that introduced threading and many related modifications to the kernel.
1.6.17 Version 5.3 Release Notes

Version 5.3.x is a development series for adding coroutining, constraints, global variables, cyclic terms (infinite trees) and other goodies to the kernel. The package JPL, providing a bidirectional Java/Prolog interface is added to the common source-tree and common binary packages.

1.6.18 Version 5.4 Release Notes

Version 5.4 consolidates the 5.3.x beta series.

1.6.19 Version 5.5 Release Notes

Version 5.5.x provides support for wide characters with UTF-8 and UNICODE I/O (section 2.17.1). On both 32 and 64-bit hardware Prolog integers are now at minimum 64-bit integers. If available, SWI-Prolog arithmetic uses the GNU GMP library to provided unbounded integer arithmetic as well as rational arithmetic. Adding GMP support is sponsored by Scientific Software and Systems Limited, www.sss.co.nz. This version also incorporates clp(r) by Christian Holzbaur, brought to SWI-Prolog by Tom Schrijvers and Leslie De Koninck (section A.8).

1.6.20 Version 5.6 Release Notes

Version 5.6 consolidates the 5.5.x beta series.

1.7 Donate to the SWI-Prolog project

If you are happy with SWI-Prolog, you care it to be around for much longer while it becomes faster, more stable and with more features you should consider to donate to the SWI-Prolog foundation. Please visit the page below.

http://www.swi-prolog.org/donate.html

1.8 Acknowledgements

Some small parts of the Prolog code of SWI-Prolog are modified versions of the corresponding Edinburgh C-Prolog code: grammar rule compilation and writef/2. Also some of the C-code originates from C-Prolog: finding the path of the currently running executable and some of the code underlying absolute_file_name/2. Ideas on programming style and techniques originate from C-Prolog and Richard O’Keefe’s thief editor. An important source of inspiration are the programming techniques introduced by Anjo Anjewierden in PCE version 1 and 2.

I also would like to thank those who had the fade of using the early versions of this system, suggested extensions or reported bugs. Among them are Anjo Anjewierden, Huub Knops, Bob Wielinga, Wouter Jansweijer, Luc Peerdeman, Eric Nombden, Frank van Harmelen, Bert Rengel.

Martin Jansche (jansche@novell1.gs.uni-heidelberg.de) has been so kind to reorganise the sources for version 2.1.3 of this manual.

Horst von Brand has been so kind to fix many typos in the 2.7.14 manual. Thanks!

Bart Demoen and Tom Schrijvers have helped me adding coroutining, constraints, global variables and support for cyclic terms to the kernel. Tom has provided the integer interval constraint solver, the CHR compiler and some of the coroutining predicates.
Paul Singleton has integrated Fred Dushin’s Java-calls-Prolog side with his Prolog-calls-Java side into the current bidirectional JPL interface package.

Richard O’Keefe is gratefully acknowledged for his efforts to educate beginners as well as valuable comments on proposed new developments.

Scientific Software and Systems Limited, www.sss.co.nz has sponsored the development if the SSL library as well as unbounded integer and rational number arithmetic.

Leslie de Koninck has made clp(QR) available to SWI-Prolog.

Markus Triska has contributed to various libraries.

Paulo Moura’s great experience in maintaining Logtalk for many Prolog systems including SWI-Prolog has helped in many places fixing compatibility issues. He also worked on the MacOS port and fixed many typos in the 5.6.9 release of the documentation.
2.1 Getting started quickly

2.1.1 Starting SWI-Prolog

Starting SWI-Prolog on Unix

By default, SWI-Prolog is installed as ‘pl’, though some administrators call it ‘swipl’ or ‘swi-prolog’. The command-line arguments of SWI-Prolog itself and its utility programs are documented using standard Unix man pages. SWI-Prolog is normally operated as an interactive application simply by starting the program:

```
machine% pl
Welcome to SWI-Prolog (Version 5.6.42)
Copyright (c) 1990-2007 University of Amsterdam.
SWI-Prolog comes with ABSOLUTELY NO WARRANTY. This is free software,
and you are welcome to redistribute it under certain conditions.
Please visit http://www.swi-prolog.org for details.

For help, use ?- help(Topic). or ?- apropos(Word).
```

`1 ?-`

After starting Prolog, one normally loads a program into it using consult/1, which — for historical reasons — may be abbreviated by putting the name of the program file between square brackets. The following goal loads the file `likes.pl` containing clauses for the predicates `likes/2`:

```
?- [likes].
% likes compiled, 0.00 sec, 596 bytes.
```

`Yes
```

After this point, Unix and Windows users unite, so if you are using Unix please continue at section 2.1.2.

Starting SWI-Prolog on Windows

After SWI-Prolog has been installed on a Windows system, the following important new things are available to the user:
• A folder (called directory in the remainder of this document) called pl containing the executables, libraries, etc. of the system. No files are installed outside this directory.

• A program plwin.exe, providing a window for interaction with Prolog. The program plcon.exe is a version of SWI-Prolog that runs in a DOS-box.

• The file-extension .pl is associated with the program plwin.exe. Opening a .pl file will cause plwin.exe to start, change directory to the directory in which the file-to-open resides and load this file.

The normal way to start with the likes.pl file mentioned in section 2.1.1 is by simply double-clicking this file in the Windows explorer.

2.1.2 Executing a query

After loading a program, one can ask Prolog queries about the program. The query below asks Prolog what food ‘sam’ likes. The system responds with $X = \langle \text{value} \rangle$ if it can prove the goal for a certain $X$. The user can type the semi-colon (;)\(^1\) if (s)he wants another solution, or RETURN if (s)he is satisfied, after which Prolog will say Yes. If Prolog answers No, it indicates it cannot find any (more) answers to the query. Finally, Prolog can answer using an error message to indicate the query or program contains an error.

```
?- likes(sam, X).
X = dahl ;
X = tandoori ;
...
X = chips ;
No
?- 
```

2.2 The user’s initialisation file

After the necessary system initialisation the system consults (see consult/1) the user’s startup file. The base-name of this file follows conventions of the operating system. On MS-Windows, it is the file pl.ini and on Unix systems .plrc. The file is searched using the file_search_path/2 clauses for user_profile. The table below shows the default value for this search-path. The phrase $\langle \text{appdata} \rangle$ refers to the Windows CSIDL name for the folder. The actual name depends on the Windows language. English versions typically use ApplicationData. See also win_folder/2

<table>
<thead>
<tr>
<th></th>
<th>Unix</th>
<th>Windows</th>
</tr>
</thead>
<tbody>
<tr>
<td>local</td>
<td>.</td>
<td>.</td>
</tr>
<tr>
<td>home</td>
<td>~</td>
<td>$\langle \text{appdata} \rangle$/SWI-Prolog</td>
</tr>
</tbody>
</table>

\(^1\)On most installations, single-character commands are executed without waiting for the RETURN key.
2.3. INITIALISATION FILES AND GOALS

After the first startup file is found it is loaded and Prolog stops looking for further startup files. The name of the startup file can be changed with the ‘-f file’ option. If File denotes an absolute path, this file is loaded, otherwise the file is searched for using the same conventions as for the default startup file. Finally, if file is none, no file is loaded.

See also the -s (script) and -F (system-wide initialisation) in section 2.4 and section 2.3.

2.3 Initialisation files and goals

Using command-line arguments (see section 2.4), SWI-Prolog can be forced to load files and execute queries for initialisation purposes or non-interactive operation. The most commonly used options are -f file or -s file to make Prolog load a file, -g goal to define an initialisation goal and -t goal to define the top-level goal. The following is a typical example for starting an application directly from the command-line.

machine% pl -s load.pl -g go -t halt

It tells SWI-Prolog to load load.pl, start the application using the entry-point go/0 and —instead of entering the interactive top-level— exit after completing go/0. The -q may be used to suppress all informational messages.

In MS-Windows, the same can be achieved using a short-cut with appropriately defined command-line arguments. A typically seen alternative is to write a file run.pl with content as illustrated below. Double-clicking run.pl will start the application.

:- [load]. % load program
:- go. % run it
:- halt. % and exit

Section 2.10.2 discusses further scripting options and chapter 10 discusses the generation of runtime executables. Runtime executables are a mean to deliver executables that do not require the Prolog system.

2.4 Command-line options

The full set of command-line options is given below:

- help
  When given as the only option, it summarises the most important options. Also available as -h and -help.

- version
  When given as the only option, it summarises the version and the architecture identifier. Also available as -v.

- arch
  When given as the only option, it prints the architecture identifier (see Prolog flag arch) and exits. See also -dump-runtime-variables. Also available as -arch.
\texttt{--dump-runtime-variables}\phantom{\texttt{--dump-runtime-variables}}

When given as the only option, it prints a sequence of variable settings that can be used in shell-scripts to deal with Prolog parameters. This feature is also used by \texttt{plld} (see section \ref{sec:plld}). Below is a typical example of using this feature. Also available as \texttt{--dump-runtime-variables}.

\begin{verbatim}
  eval 'pl --dump-runtime-variables'
  cc -I$PLBASE/include -L$PLBASE/runtime/$PLARCH ...
\end{verbatim}

The option can be followed by \texttt{=sh} to dump in POSIX shell format (default) or \texttt{cmd} to dump in MS-Windows \texttt{cmd.exe} compatible format.

\texttt{--win}\phantom{\texttt{--win}}

This option is available only in \texttt{plwin.exe} and is used for the start-menu item. If causes \texttt{plwin} to start in the folder \ldots\My\Documents\Prolog or local equivalent thereof (see \texttt{win_folder/2}). The Prolog subdirectory is created if it does not exist.

\texttt{--quiet}\phantom{\texttt{--quiet}}

Set the Prolog flag \texttt{verbose} to \texttt{silent}, suppressing informational and banner messages. Also available as \texttt{--q}.

\texttt{\textbf{-Lsize[kmg]}}

Give local stack limit (default 16Mb on 32-bit and 32Mb on 64-bit hardware). Note that there is no space between the size option and its argument. By default, the argument is interpreted in Kbytes. Postfix the argument with \texttt{m} for Mbytes or \texttt{g} for Gbytes. The following example specifies 64 Mbytes local stack.

\begin{verbatim}
  % pl -L64m
\end{verbatim}

A maximum is useful to stop buggy programs from claiming all memory resources. \texttt{-L0} sets the limit to the highest possible value.\footnote{On 64-bit systems there is no relevant limit and \texttt{-L0} is interpreted as 1Gb. It is possible to ask for larger stack-sizes such as \texttt{-L32g}} See section \ref{sec:stack limits}.

\texttt{\textbf{-Gsize[kmg]}}

Give global stack limit (4 Mbytes default). See \texttt{-L} for more details.

\texttt{\textbf{-Tsize[kmg]}}

Give trail stack limit (4 Mbytes default). This limit is relatively high because trail-stack overflows are not often caused by program bugs. See \texttt{-L} for more details.

\texttt{\textbf{-Asize[kmg]}}

Give argument stack limit (1 Mbytes default). The argument stack limits the maximum nesting of terms that can be compiled and executed. SWI-Prolog does ‘last-argument optimisation’ to avoid many deeply nested structure using this stack. Enlarging this limit is only necessary in extreme cases. See \texttt{-L} for more details.

\texttt{-c file \ldots}\phantom{-c file \ldots}

Compile files into an ‘intermediate code file’. See section \ref{sec:intermediate code}.\footnote{Compile files into an ‘intermediate code file’. See section \ref{sec:intermediate code}}
### 2.4. COMMAND-LINE OPTIONS

- **-o output**
  Used in combination with `-c` or `-b` to determine output file for compilation.

- **-O**
  Optimised compilation. See `current_prolog_flag/2` flag `optimise` for details.

- **--nodebug**
  Disable debugging. See the `current_prolog_flag/2` flag `generate_debug_info` for details.

- **-s file**
  Use `file` as a script-file. The script file is loaded after the initialisation file specified with the `-f file` option. Unlike `-f file`, using `-s` does not stop Prolog from loading the personal initialisation file.

- **-f file**
  Use `file` as initialisation file instead of the default `.plrc` (Unix) or `pl.ini` (Windows). `-f none` stops SWI-Prolog from searching for a startup file. This option can be used as an alternative to `-s file` that stops Prolog from loading the personal initialisation file. See also section 2.2.

- **-F script**
  Selects a startup-script from the SWI-Prolog home directory. The script-file is named `⟨script⟩.rc`. The default `script` name is deduced from the executable, taking the leading alphanumerical characters (letters, digits and underscore) from the program-name. `-F none` stops looking for a script. Intended for simple management of slightly different versions. One could for example write a script `iso.rc` and then select ISO compatibility mode using `pl -F iso` or make a link from `iso-pl` to `pl`.

- **-g goal**
  
  `Goal` is executed just before entering the top level. Default is a predicate which prints the welcome message. The welcome message can thus be suppressed by giving `-g true. goal` can be a complex term. In this case quotes are normally needed to protect it from being expanded by the shell. A save way to run a goal non-interactively is here:

  ```
  % pl <options> -g go,halt -t 'halt(1)'
  ```

- **-t goal**
  
  Use `goal` as interactive top-level instead of the default goal `prolog/0`. `goal` can be a complex term. If the top-level goal succeeds SWI-Prolog exits with status 0. If it fails the exit status is 1. If the toplevel raises an exception, this is printed as an uncaught error and the toplevel is restarted. This flag also determines the goal started by `break/0` and `abort/0`. If you want to stop the user from entering interactive mode start the application with ‘-g goal’ and give ‘halt’ as top-level.

- **-tty**
  
  Unix only. Switches controlling the terminal for allowing single-character commands to the tracer and `get_single_char/1`. By default manipulating the terminal is enabled unless the system detects it is not connected to a terminal or it is running as a GNU-Emacs inferior process. This flag is sometimes required for smooth interaction with other applications.
–nosignals
Inhibit any signal handling by Prolog, a property that is sometimes desirable for embedded applications. This option sets the flag signals to false. See section 9.6.20 for details.

–home=DIR
Use DIR as home directory. See section 9.8 for details.

-x bootfile
Boot from bootfile instead of the system’s default boot file. A bootfile is a file resulting from a Prolog compilation using the -b or -c option or a program saved using qsave_program/[1,2].

-p alias=path1[:path2 ...]
Define a path alias for file_search_path. alias is the name of the alias, path1 ... is a list of values for the alias. On Windows the list-separator is ;. On other systems it is :. A value is either a term of the form alias(value) or pathname. The computed aliases are added to file_search_path/2 using asserta/1, so they precede predefined values for the alias. See file_search_path/2 for details on using this file-location mechanism.

--
Stops scanning for more arguments, so you can pass arguments for your application after this one. See current_prolog_flag/2 using the flag argv for obtaining the command-line arguments.

The following options are for system maintenance. They are given for reference only.

-b initfile ... -c file ...
Boot compilation. initfile ... are compiled by the C-written bootstrap compiler, file ... by the normal Prolog compiler. System maintenance only.

-d level
Set debug level to level. Only has effect if the system is compiled with the -D_DEBUG flag. System maintenance only.

2.5 GNU Emacs Interface
The default Prolog mode for GNU-Emacs can be activated by adding the following rules to your Emacs initialisation file:

```
(setq auto-mode-alist
   (append
    `(("\.pl" . prolog-mode))
   auto-mode-alist))
(setq prolog-program-name "pl")
(setq prolog-consult-string "[user].\n")
;if you want this. Indentation is either poor or I don’t use
;it as intended.
;(setq prolog-indent-width 8)
```

2.6 Online Help

Online help provides a fast lookup and browsing facility to this manual. The online manual can show predicate definitions as well as entire sections of the manual.

The online help is displayed from the file ‘MANUAL’. The file helpidx provides an index into this file. ‘MANUAL’ is created from the \LaTeX{} sources with a modified version of dvitty, using overstrike for printing bold text and underlining for rendering italic text. XPCE is shipped with swi.help, presenting the information from the online help in a hypertext window. The Prolog flag write_help_with_overstrike controls whether or not help/1 writes its output using overstrike to realise bold and underlined output or not. If this Prolog flag is not set it is initialised by the help library to true if the TERM variable equals xterm and false otherwise. If this default does not satisfy you, add the following line to your personal startup file (see section 2.2):

:- set_prolog_flag(write_help_with_overstrike, true).

help

Equivalent to help(help/1).

help(+What)

Show specified part of the manual. What is one of:

¡Name¿/(Arity) Give help on specified predicate
¡Name¿ Give help on named predicate with any arity or C interface function with that name
¡Section¿ Display specified section. Section numbers are dash-separated numbers: 2-3 refers to section 2.3 of the manual. Section numbers are obtained using apropos/1.

Examples:

?- help(assert). Give help on predicate assert
?- help(3-4). Display section 3.4 of the manual
?- help('PL_retry'). Give help on interface function PL_retry()

See also apropos/1, and the SWI-Prolog home page at http://www.swi-prolog.org, which provides a FAQ, an HTML version of manual for online browsing and HTML and PDF versions for downloading.

apropos(+Pattern)

Display all predicates, functions and sections that have Pattern in their name or summary description. Lowercase letters in Pattern also match a corresponding uppercase letter. Example:
Table 2.1: History commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>!.</td>
<td>Repeat last query</td>
</tr>
<tr>
<td>!nr.</td>
<td>Repeat query numbered (nr)</td>
</tr>
<tr>
<td>!str.</td>
<td>Repeat last query starting with (str)</td>
</tr>
<tr>
<td>h.</td>
<td>Show history of commands</td>
</tr>
<tr>
<td>!h.</td>
<td>Show this list</td>
</tr>
</tbody>
</table>

?- apropos(file). Display predicates, functions and sections that have ‘file’ (or ‘File’, etc.) in their summary description.

explain(+ToExplain)
Give an explanation on the given ‘object’. The argument may be any Prolog data object. If the argument is an atom, a term of the form Name/Arity or a term of the form Module:Name/Arity, explain/1 describes the predicate as well as possible references to it. See also gxref/0.

explain(+ToExplain, -Explanation)
Unify Explanation with an explanation for ToExplain. Backtracking yields further explanations.

2.7 Command-line history
SWI-Prolog offers a query substitution mechanism called ‘history’. The availability of this feature is controlled by set_prolog_flag/2, using the history Prolog flag. By default, history is available if the Prolog flag readline is false. To enable this feature, remembering the last 50 commands, put the following into your startup file (see section 2.2):

```prolog
:- set_prolog_flag(history, 50).
```

The history system allows the user to compose new queries from those typed before and remembered by the system. The available history commands are shown in table 2.1. History expansion is not done if these sequences appear in quoted atoms or strings.

2.8 Reuse of top-level bindings
Bindings resulting from the successful execution of a top-level goal are asserted in a database. These values may be reused in further top-level queries as $Var. Only the latest binding is available. Example:

Note that variables may be set by executing =/2:

6 ?- X = statistics.
X = statistics
Yes
7 ?- $X.
28.00 seconds cpu time for 183,128 inferences
2.9. OVERVIEW OF THE DEBUGGER

1 ?- maplist(plus(1), "hello", X).
X = [105,102,109,109,112]
Yes
2 ?- format(’~s~n’, [$X]).
ifmmp
Yes
3 ?-

Figure 2.1: Reusing top-level bindings

4,016 atoms, 1,904 functors, 2,042 predicates, 52 modules
55,915 byte codes; 11,239 external references

<table>
<thead>

2.9 Overview of the Debugger

SWI-Prolog has a 6-port tracer, extending the standard 4-port Byrd box model tracer [Byrd, 1980, Clocksin & Melish, 1987] with two additional ports. The optional unify port allows the user to inspect the result after unification of the head. The exception port shows exceptions raised by throw/1 or one of the built-in predicates. See section 4.9.

The standard ports are called call, exit, redo, fail and unify. The tracer is started by the trace/0 command, when a spy point is reached and the system is in debugging mode (see spy/1 and debug/0) or when an exception is raised.

The interactive top-level goal trace/0 means “trace the next query”. The tracer shows the port, displaying the port name, the current depth of the recursion and the goal. The goal is printed using the Prolog predicate write_term/2. The style is defined by the Prolog flag debugger_print_options and can be modified using this flag or using the w, p and d commands of the tracer.

On leashed ports (set with the predicate leash/1, default are call, exit, redo and fail) the user is prompted for an action. All actions are single character commands which are executed without waiting for a return, unless the command-line option -tty is active. Tracer options:

+ (Spy)
Set a spy point (see spy/1) on the current predicate.
1 ?- visible(+all), leash(-exit).
   Yes
2 ?- trace, min([3, 2], X).
   Call: (3) min([3, 2], G235) ? creep
   Unify: (3) min([3, 2], G235)
   Call: (4) min([2], G244) ? creep
   Unify: (4) min([2], 2)
   Exit: (4) min([2], 2)
   Call: (4) min(3, 2, G235) ? creep
   Unify: (4) min(3, 2, G235)
   Call: (5) 3 < 2 ? creep
   Fail: (5) 3 < 2 ? creep
   Redo: (4) min(3, 2, G235) ? creep
   Exit: (4) min(3, 2, 2)
   Exit: (3) min([3, 2], 2)
   Yes

[trace] 3 ?-

Figure 2.2: Example trace

- (No spy)
  Remove the spy point (see nospy/1) from the current predicate.

/ (Find)
  Search for a port. After the ‘/’, the user can enter a line to specify the port to search for. This
  line consists of a set of letters indicating the port type, followed by an optional term, that should
  unify with the goal run by the port. If no term is specified it is taken as a variable, searching for
  any port of the specified type. If an atom is given, any goal whose functor has a name equal to
  that atom matches. Examples:

  /f Search for any fail port
  /fe solve Search for a fail or exit port of any goal with name
  solve
  /c solve(a, _) Search for a call to solve/2 whose first argument
  is a variable or the atom a
  /a member(_, _) Search for any port on member/2. This is equiv-
  alent to setting a spy point on member/2.

. (Repeat find)
  Repeat the last find command (see ‘/’).

A (Alternatives)
  Show all goals that have alternatives.

C (Context)
2.9. OVERVIEW OF THE DEBUGGER

Toggle ‘Show Context’. If on, the context module of the goal is displayed between square brackets (see section 5). Default is off.

L (Listing)
List the current predicate with listing/1.

a (Abort)
Abort Prolog execution (see abort/0).

b (Break)
Enter a Prolog break environment (see break/0).

c (Creep)
Continue execution, stop at next port. (Also return, space).

d (Display)
Set the max_depth(Depth) option of debugger_print_options, limiting the depth to which terms are printed. See also the w and p options.

e (Exit)
Terminate Prolog (see halt/0).

f (Fail)
Force failure of the current goal.

g (Goals)
Show the list of parent goals (the execution stack). Note that due to tail recursion optimization a number of parent goals might not exist any more.

h (Help)
Show available options (also ‘?’).

i (Ignore)
Ignore the current goal, pretending it succeeded.

l (Leap)
Continue execution, stop at next spy point.

n (No debug)
Continue execution in ‘no debug’ mode.

p (Print)
Set the Prolog flag debugger_print_options to [quoted(true), portray(true), max_depth(10), priority(699)]. This is the default.

r (Retry)
Undo all actions (except for database and i/o actions) back to the call port of the current goal and resume execution at the call port.

s (Skip)
Continue execution, stop at the next port of this goal (thus skipping all calls to children of this goal).
u (Up)
Continue execution, stop at the next port of the parent goal (thus skipping this goal and all calls to children of this goal). This option is useful to stop tracing a failure driven loop.

w (Write)
Set the Prolog flag `debugger_print_options` to `[quoted(true), attributes(write), priority(699)]`, bypassing `portray/1`, etc.

The ideal 4 port Byrd box model [Byrd, 1980] as described in many Prolog books [Clocksin & Melish, 1987] is not visible in many Prolog implementations because code optimisation removes part of the choice- and exit-points. Backtrack points are not shown if either the goal succeeded deterministically or its alternatives were removed using the cut. When running in debug mode (`debug/0`) choice points are only destroyed when removed by the cut. In debug mode, last call optimisation is switched off.\(^3\)

Reference information to all predicates available for manipulating the debugger is in section 4.38.

### 2.10 Compilation

#### 2.10.1 During program development

During program development, programs are normally loaded using `consult/1`, or the list abbreviation. It is common practice to organise a project as a collection of source files and a `load-file`, a Prolog file containing only `use_module/[1,2]` or `ensure_loaded/1` directives, possibly with a definition of the entry-point of the program, the predicate that is normally used to start the program. This file is often called `load.pl`. If the entry-point is called `go`, a typical session starts as:

```
% pl
<banner>
1 ?- [load].
<compilation messages>
Yes
2 ?- go.
<program interaction>
```

When using Windows, the user may open `load.pl` from the Windows explorer, which will cause `plwin.exe` to be started in the directory holding `load.pl`. Prolog loads `load.pl` before entering the top-level.

#### 2.10.2 For running the result

There are various options if you want to make your program ready for real usage. The best choice depends on whether the program is to be used only on machines holding the SWI-Prolog development system, the size of the program and the operating system (Unix vs. Windows).

\(^3\)This implies the system can run out of local stack in debug mode, while no problems arise when running in non-debug mode.
Using PrologScript

New in version 4.0.5 is the possibility to use a Prolog source file directly as a Unix script-file. The same mechanism is useful to specify additional parameters for running a Prolog file on Windows.

If the first letter of a Prolog file is #, the first line is treated as comment.\(^4\) To create a Prolog script, make the first line start like this:

```bash
#!/path/to/pl ⟨options⟩ -s
```

Prolog recognises this starting sequence and causes the interpreter to receive the following argument-list:

```bash
/path/to/pl ⟨options⟩ -s ⟨script⟩ -- ⟨ScriptArguments⟩
```

Instead of -s, the user may use -f to stop Prolog from looking for a personal initialisation file.

Here is a simple script doing expression evaluation:

```bash
#!/usr/bin/pl -q -t main -f

eval :-
    current_prolog_flag(argv, Argv),
    append(_, [|--|Args], Argv),
    concat_atom(Args, ' ', SingleArg),
    term_to_atom(Term, SingleArg),
    Val is Term,
    format('˜w˜n', [Val]).

main :-
    catch(eval, E, (print_message(error, E), fail)),
    halt.

main :-
    halt(1).
```

And here are two example runs:

```
% eval 1+2
3
% eval foo
ERROR: Arithmetic: ‘foo/0’ is not a function
%
```

\(^4\)The #-sign can be the legal start of a normal Prolog clause. In the unlikely case this is required, leave the first line blank or add a header-comment.
The Windows version supports the `#!` construct too, but here it serves a rather different role. The Windows shell already allows the user to start Prolog source files directly through the Windows file-type association. Windows however makes it rather complicated to provide additional parameters, such as the required stack-size for an individual Prolog file. The `#!` line provides for this, providing a more flexible approach than changing the global defaults. The following starts Prolog with unlimited stack-size on the given source file:

```shell
#!/usr/bin/pl -L0 -T0 -G0 -s
```

Note the use of `/usr/bin/pl`, which specifies the interpreter. This argument is ignored in the Windows version, but required to ensure best cross-platform compatibility.

Creating a shell-script

With the introduction of PrologScript (see section 2.10.2), using shell-scripts as explained in this section has become redundant for most applications.

Especially on Unix systems and not-too-large applications, writing a shell-script that simply loads your application and calls the entry-point is often a good choice. A skeleton for the script is given below, followed by the Prolog code to obtain the program arguments.

```shell
#!/bin/sh
base=<absolute-path-to-source>
PL=pl
exec $PL -f none -g "load_files(['$base/load'],[silent(true)])" \\
   -t go -- $*
```

```prolog
go :-
    current_prolog_flag(argv, Arguments),
    append(_SytemArgs, [--|Args], Arguments), !,
    go(Arg).

go(Arg) :-
    ...```

On Windows systems, similar behaviour can be achieved by creating a shortcut to Prolog, passing the proper options or writing a `.bat` file.

Creating a saved-state

For larger programs, as well as for programs that are required to run on systems that do not have the SWI-Prolog development system installed, creating a saved state is the best solution. A saved state is created using `gsave_program/[1,2]` or using the linker `plld(1)`. A saved state is a file containing machine-independent intermediate code in a format dedicated for fast loading. Optionally, the emulator may be integrated in the saved state, creating a single-file, but machine-dependent, executable. This process is described in chapter 10.
Compilation using the -c command-line option

This mechanism loads a series of Prolog source files and then creates a saved-state as qsave_program/2 does. The command syntax is:

```bash
% pl [option ...] [-o output] -c file ...
```

The `options` argument are options to qsave_program/2 written in the format below. The option-names and their values are described with qsave_program/2.

```
--option-name=option-value
```

For example, to create a stand-alone executable that starts by executing main/0 and for which the source is loaded through load.pl, use the command

```bash
% pl --goal=main --stand_alone=true -o myprog -c load.pl
```

This performs exactly the same as executing

```bash
% pl
<banner>
?- [load].
?- qsave_program(myprog,
    [ goal(main),
      stand_alone(true)
    ]).
?- halt.
```

### 2.11 Environment Control (Prolog flags)

The predicates `current_prolog_flag/2` and `set_prolog_flag/2` allow the user to examine and modify the execution environment. It provides access to whether optional features are available on this version, operating system, foreign-code environment, command-line arguments, version, as well as runtime flags to control the runtime behaviour of certain predicates to achieve compatibility with other Prolog environments.

#### `current_prolog_flag(Key, Value)`  

The predicate `current_prolog_flag/2` defines an interface to installation features: options compiled in, version, home, etc. With both arguments unbound, it will generate all defined Prolog flags. With the ‘Key’ instantiated it unifies the value of the Prolog flag. Flag values are typed. Flags marked as `bool` can have the values `true` and `false`. Some Prolog flags are not defined in all versions, which is normally indicated in the documentation below as “if present and true”. A Boolean Prolog flag is true iff the Prolog flag is present `and` the `Value` is the atom `true`. Tests for such flags should be written as below.

```prolog
{ current_prolog_flag(windows, true) -> <Do MS-Windows things> ; <Do normal things> }
```
abort_with_exception (bool, changeable)
Determines how abort/0 is realised. See the description of abort/0 for details.

address_bits (integer)
Address-size of the hosting machine. Typically 32 or 64. Except for the maximum stack limit, this has few implications to the user. See also the Prolog flag arch.

age_margin (integer, changeable)
If this amount of atoms has been created since the last atom-garbage collection, perform atom garbage collection at the first opportunity. Initial value is 10,000. May be changed. A value of 0 (zero) disables atom garbage collection. See also PL_register_atom().

allow_variable_name_as_functor (bool, changeable)
If true (default is false), Functor(arg) is read as if it was written ’Functor’ (arg). Some applications use the Prolog read/1 predicate for reading an application defined script language. In these cases, it is often difficult to explain to non-Prolog users of the application that constants and functions can only start with a lowercase letter. Variables can be turned into atoms starting with an uppercase atom by calling read_term/2 using the option variable_names and binding the variables to their name. Using this feature, F(x) can be turned into valid syntax for such script languages. Suggested by Robert van Engelen. SWI-Prolog specific.

argv (list)
List is a list of atoms representing the command-line arguments used to invoke SWI-Prolog. Please note that all arguments are included in the list returned.

arch (atom)
Identifier for the hardware and operating system SWI-Prolog is running on. Used to select foreign files for the right architecture. See also section 9.4 and file_search_path/2.

associate (atom, changeable)
On Windows systems, this is set to the filename extension (pl (default) or pro (can be selected in the installer)) associated with plwin.exe.

autoload (bool, changeable)
If true (default) autoloading of library functions is enabled. Note that autoloading only works if the flag unknown is not set to fail. See section 2.13.

backquoted_string (bool, changeable)
If true (default false), read translates text between backquotes into a string object (see section 4.23). This flag is mainly for compatibility to LPA Prolog.

bounded (bool)
ISO Prolog flag. If true, integer representation is bound by min_integer and max_integer. If false integers can be arbitrarily large and the min_integer and max_integer are not present. See section 4.26.2.

c_cc (atom)
Name of the C-compiler used to compile SWI-Prolog. Normally either gcc or cc. See section 9.7.

c_ldflags (atom)
Special linker flags passed to link SWI-Prolog. See section 9.7.

c_libs (atom)
Libraries passed to the C-linker when SWI-Prolog was linked. May be used to determine the libraries needed to create statically linked extensions for SWI-Prolog. See section 9.7.
2.11. ENVIRONMENT CONTROL (PROLOG FLAGS)

char_conversion (bool, changeable)
Determines whether character-conversion takes place while reading terms. See also
char_conversion/2.

character_escapes (bool, changeable)
If true (default), read/1 interprets \ escape sequences in quoted atoms and strings.
May be changed. This flag is local to the module in which it is changed.

compiled_at (atom)
Describes when the system has been compiled. Only available if the C-compiler used to
compile SWI-Prolog provides the _DATE_ and _TIME_ macros.

console_menu (bool)
Set to true in plwin.exe to indicate the console supports menus. See also
section 4.34.2.

cpu_count (integer, changeable)
Number of physical CPUs in the system. Unfortunately there is no standard to get this
number, so on most operating systems this flag is not available. It is marked read-write
both to allow obtaining this value later and to allow pretending the system has more or
less processors. See also thread_setconcurrency/2 and the library thread.
Currently this flag is supported in Windows and Linux if /proc is enabled. If you can
provide us with a C-code fragment getting the number for a specific OS, please submit an
enhancement report at http://gollem.science.uva.nl/bugzilla/

dde (bool)
Set to true if this instance of Prolog supports DDE as described in section 4.42.

debug (bool, changeable)
Switch debugging mode on/off. If debug mode is activated the system traps encountered
spy-points (see spy/1) and trace-points (see trace/1). In addition, last-call optimi-
sation is disabled and the system is more conservative in destroying choice points to
simplify debugging.
Disabling these optimisations can cause the system to run out of memory on programs
that behave correctly if debug mode is off.

debug_on_error (bool, changeable)
If true, start the tracer after an error is detected. Otherwise just continue execution. The
goal that raised the error will normally fail. See also fileerrors/2 and the Prolog
flag report_error. May be changed. Default is true, except for the runtime version.

debugger_print_options (term, changeable)
This argument is given as option-list to write_term/2 for printing goals by the de-
bugger. Modified by the ‘w’, ‘p’ and ‘⟨N⟩ d’ commands of the debugger. Default is
[quoted(true), portray(true), max_depth(10), attributes(portray)].

debugger_show_context (bool, changeable)
If true, show the context module while printing a stack-frame in the tracer. Normally
trolled using the ‘C’ option of the tracer.

dialect (atom)
Fixed to swi. The code below is a reliable and portable way to detect SWI-Prolog.

     is_dialect(swi) :-
        catch(current_prolog_flag(dialect, swi), _, fail).
**double_quotes** *(codes, chars, atom, string, changeable)*

This flag determines how double quoted strings are read by Prolog and is —like `character_escapes`— maintained for each module. If `codes` (default), a list of character-codes is returned, if `chars` a list of one-character atoms, if `atom` double quotes are the same as single-quotes and finally, `string` reads the text into a Prolog string (see section 4.23). See also `atom_chars/2` and `atom_codes/2`.

**dynamic_stacks** *(bool)*

If `true`, the system uses some form of ‘sparse-memory management’ to realise the stacks. If false, `malloc()`/`realloc()` are used for the stacks. In earlier days this had consequences for foreign code. As of version 2.5, this is no longer the case.

Systems using ‘sparse-memory management’ are a bit faster as there is no stack-shifter. On most systems using sparse-memory management memory is actually returned to the system after a garbage collection or call to `trim_stacks/0` (called by `prolog/0` after finishing a user-query).

**editor** *(atom, changeable)*

Determines the editor used by `edit/1`. See section 4.4 for details on selecting the editor used.

**emacs_inferior_process** *(bool)*

If `true`, SWI-Prolog is running as an *inferior process* of (GNU/X-)Emacs. SWI-Prolog assumes this is the case if the environment variable `EMACS` is `t` and `INFERIOR` is `yes`.

**encoding** *(atom, changeable)*

Default encoding used for opening files in `text` mode. The initial value is deduced from the environment. See section 2.17.1 for details.

**executable** *(atom)*

Path-name of the running executable. Used by `qsave_program/2` as default emulator.

**file_name_variables** *(bool, changeable)*

If `true` (default false), expand `$varname` and `~` in arguments of built-in predicates that accept a file name (`open/3`, `exists_file/1`, `access_file/2`, etc.). The predicate `expand_file_name/2` can be used to expand environment variables and wildcard patterns. This Prolog flag is intended for backward compatibility with older versions of SWI-Prolog.

**float_format** *(atom, changeable)*

C-library `printf()` format specification used by `write/1` and friends to determine how floating point numbers are printed. The default is `%g`. The specified value is passed to `printf()` without further checking. For example, if you want more digits printed, `%.12g` will print all floats using 12 digits instead of the default 6.

When using quoted-write, the output is guaranteed to contain a decimal dot or exponent, so `read/1` reads a floating point number. See also `format/[1,2]`, `write_term/[2,3]`.

**gc** *(bool, changeable)*

If `true` (default), the garbage collector is active. If false, neither garbage-collection, nor stack-shifts will take place, even not on explicit request. May be changed.

**generate_debug_info** *(bool, changeable)*

If `true` (default) generate code that can be debugged using `trace/0`, `spy/1`, etc. Can
be set to false using the -nodebug. The predicate load_files/2 restores the value of this flag after loading a file, causing modifications to be local to a source file. Many of the libraries have :- set_prolog_flag(generate_debug_info, false) to hide their details from a normal trace.\footnote{In the current implementation this only causes a flag to be set on the predicate that causes children to be hidden from the debugger. The name anticipates on anticipated changes to the compiler.}

**gmp_version** (integer)
If Prolog is linked with GMP, this flag gives the major version of the GMP library used. See also section 9.6.7.

**gui** (bool)
Set to true if XPCE is around and can be used for graphics.

**history** (integer, changeable)
If integer > 0, support Unix csh(1) like history as described in section 2.7. Otherwise, only support reusing commands through the command-line editor. The default is to set this Prolog flag to 0 if a command-line editor is provided (see Prolog flag readline) and 15 otherwise.

**home** (atom)
SWI-Prolog’s notion of the home-directory. SWI-Prolog uses its home directory to find its startup file as ⟨home⟩/boot32.prc (32-bit machines) or ⟨home⟩/boot64.prc (64-bit machines) and to find its library as ⟨home⟩/library.

**hwnd** (integer)
In plwin.exe, this refers to the MS-Windows window-handle of the console window.

**integer_rounding_function** (down,toward_zero)
ISO Prolog flag describing rounding by // and rem arithmetic functions. Value depends on the C-compiler used.

**iso** (bool, changeable)
Include some weird ISO compatibility that is incompatible to normal SWI-Prolog behaviour. Currently it has the following effect:

- The //2 (float division) always return a float, even if applied to integers that can be divided.
- In the standard order of terms (see section 4.6.1), all floats are before all integers.
- atom_length/2 yields an instantiation error if the first argument is a number.
- clause/[2,3] raises a permission error when accessing static predicates.
- abolish/[1,2] raises a permission error when accessing static predicates.

**large_files** (bool)
If present and true, SWI-Prolog has been compiled with large file support (LFS) and is capable to access files larger than 2GB on 32-bit hardware. Large file-support is default on installations built using configure that support it and may be switched off using the configure option --disable-largefile.

**max arity** (unbounded)
ISO Prolog flag describing there is no maximum arity to compound terms.

**max_integer** (integer)
Maximum integer value if integers are bounded. See also the flag bounded and section 4.26.2.
**max_tagged_integer (integer)**

Maximum integer value represented as a ‘tagged’ value. Tagged integers require 1 word storage. Larger integers are represented as ‘indirect data’ and require significantly more space.

**max_threads (integer)**

Provided on multi-threaded versions to indicate the maximum number of Prolog threads supported. Currently (version 5.6.27) the limit is 100.

**min_integer (integer)**

Minimum integer value if integers are bounded. See also the flag bounded and section 4.26.2.

**min_tagged_integer (integer)**

Start of the tagged-integer value range.

**occurs_check (atom, changeable)**

This flag controls unification that creates an infinite tree (also called cyclic term) and can have three values. Using false (default), unification succeeds, creating an infinite tree. Using true, unification behaves as unify_with_occurs_check/2, failing silently. Using error, an attempt to create a cyclic term results in an occurs_check exception. The latter is intended for debugging unintentional creations of cyclic terms. Note that this flag is a global flag modifying fundamental behaviour of Prolog. Changing the flag from its default may cause libraries to stop functioning properly.

**open_shared_object (bool)**

If true, open_shared_object/2 and friends are implemented, providing access to shared libraries (.so files) or dynamic link libraries (.DLL files).

**optimise (bool, changeable)**

If true, compile in optimised mode. The initial value is true if Prolog was started with the -O command-line option.

Currently optimise compilation implies compilation of arithmetic, and deletion of redundant true/0 that may result from expand_goal/2.

Later versions might imply various other optimisations such as integrating small predicates into their callers, eliminating constant expressions and other predictable constructs. Source code optimisation is never applied to predicates that are declared dynamic (see dynamic/1).

**pid (int)**

Process identifier of the running Prolog process. Existence of this flag is implementation defined.

**pipe (bool, changeable)**

If true, open(pipe(command), mode, Stream), etc. are supported. Can be changed to disable the use of pipes in applications testing this feature. Not recommended.

**prompt_alternatives_on (atom, changeable)**

Determines prompting for alternatives in the Prolog toplevel. Default is determinism, which implies the system prompts for alternatives if the goal succeeded while leaving choicepoints. Many classical Prolog systems behave as groundness: they prompt for alternatives if and only if the query contains variables.
2.11. ENVIRONMENT CONTROL (PROLOG FLAGS) 41

**readline (bool)**
If true, SWI-Prolog is linked with the readline library. This is done by default if you have this library installed on your system. It is also true for the Win32 plwin.exe version of SWI-Prolog, which realises a subset of the readline functionality.

**resource_database (atom)**
Set to the absolute-filename of the attached state. Typically this is the file `boot32.prc`, the file specified with -x or the running executable. See also resource/3.

**report_error (bool, changeable)**
If true, print error messages, otherwise suppress them. May be changed. See also the debug_on_error Prolog flag. Default is true, except for the runtime version.

**runtime (bool)**
If present and true, SWI-Prolog is compiled with -DO_RUNTIME, disabling various useful development features (currently the tracer and profiler).

**saved_program (bool)**
If present and true, Prolog has been started from a state saved with qsave_program/[1,2].

**shared_object_extension (atom)**
Extension used by the operating system for shared objects. .so for most Unix systems and .dll for Windows. Used for locating files using the file_type executable. See also absolute_file_name/3.

**shared_object_search_path (atom)**
Name of the environment variable used by the system to search for shared objects.

**signals (bool)**
Determine whether Prolog is handling signals (software interrupts). This flag is false if the hosting OS does not support signal handling or the command-line option -nosignals is active. See section 9.6.20 for details.

**system_thread_id (int)**
Available in multi-threaded version (see section 8) where the operating system provides system-wide integer thread identifiers. The integer is the thread-identifier used by the operating system for the calling thread. See also thread_self/1.

**last_call_optimisation (bool, changeable)**
Determines whether or not last-call optimisation is enabled. Normally the value of this flag is equal to the debug flag. As programs may run out of stack if last-call optimisation is omitted, it is sometimes necessary to enable it during debugging.

**timezone (integer)**
Offset in seconds west of GMT of the current time-zone. Set at initialization time from the timezone variable associated with the POSIX tzset() function. See also convert_time/2.

**toplevel_print_anon (bool, changeable)**
If true, top-level variables starting with an underscore (_) are printed normally. If false they are hidden. This may be used to hide bindings in complex queries from the top-level.

**toplevel_print_options (term, changeable)**
This argument is given as option-list to write_term/2 for printing results of queries. Default is [quoted(true), portray(true), max_depth(10), attributes(portray)].
**toplevel_var_size** (*int, changeable*)

Maximum size counted in literals of a term returned as a binding for a variable in a top-level query that is saved for re-use using the $ variable reference. See section 2.8.

**trace_gc** (*bool, changeable*)

If true (false is the default), garbage collections and stack-shifts will be reported on the terminal. May be changed. Values are reported in bytes as $G+T$, where $G$ is the global stack value and $T$ the trail stack value. ‘Gained’ describes the number of bytes reclaimed. ‘used’ the number of bytes on the stack after GC and ‘free’ the number of bytes allocated, but not in use. Below is an example output.

% GC: gained 236,416+163,424 in 0.00 sec; used 13,448+5,808; free 72,568+47,440

**tty_control** (*bool*)

Determines whether the terminal is switched to raw mode for `get_single_char/1`, which also reads the user-actions for the trace. May be set. See also the `+/-tty` command-line option.

**unix** (*bool*)

If present and true, the operating system is some version of Unix. Defined if the C-compiler used to compile this version of SWI-Prolog either defines __unix__ or unix. On other systems this flag is not available.

**unknown** (*fail, warning, error, changeable*)

Determines the behaviour if an undefined procedure is encountered. If fail, the predicates fails silently. If warn, a warning is printed, and execution continues as if the predicate was not defined and if error (default), an existence_error exception is raised. This flag is local to each module. Switching this flag to fail disables autoloading and thus forces complete and consistent use of `use_module/[1,2]` to load the required libraries.

**verbose** (*Atom, changeable*)

This flags is used by `print_message/2`. If its value is silent, messages of type informational and banner are suppressed. The -q switches the value from the initial normal to silent.

**verbose_autoload** (*bool, changeable*)

If true the normal consult message will be printed if a library is autoloaded. By default this message is suppressed. Intended to be used for debugging purposes.

**verbose_load** (*bool, changeable*)

If false normal consult messages will be suppressed. Default is true. The value of this flag is normally controlled by the option `silent(Bool)` provided by `load_files/2`.

**verbose_file_search** (*bool, changeable*)

If true (default false), print messages indicating the progress of `absolute_file_name/[2,3]` in locating files. Intended for debugging complicated file-search paths. See also `file_search_path/2`.

**version** (*integer*)

The version identifier is an integer with value:

$$10000 \times \text{Major} + 100 \times \text{Minor} + \text{Patch}$$
Note that in releases up to 2.7.10 this Prolog flag yielded an atom holding the three numbers separated by dots. The current representation is much easier for implementing version-conditional statements.

**version data** *(swi(Major, Minor, Patch, Extra))*

Part of the dialect compatibility layer. See also the Prolog flag *dialect* and section C. *Extra* provides platform specific version information. Currently it is simply unified to [].

**version git** *(atom)*

Available if created from a git repository. See git-describe for details.

**windows** *(bool)*

If present and true, the operating system is an implementation of Microsoft Windows (NT/2000/XP, etc.). This flag is only available on MS-Windows based versions.

**write attributes** *(atom, changeable)*

Defines how write/1 and friends write attributed variables. The option values are described with the attributes option of write_term/3. Default is ignore.

**write help with overstrike** *(bool)*

Internal flag used by help/1 when writing to a terminal. If present and true it prints bold and underlined text using overstrike.

**xpce** *(bool)*

Available and set to true if the XPCE graphics system is loaded.

**xpce version** *(atom)*

Available and set to the version of the loaded XPCE system.

**set prolog flag** *(+Key, +Value)*

[ISO] Define a new Prolog flag or change its value. *Key* is an atom. If the flag is a system-defined flag that is not marked changeable above, an attempt to modify the flag yields a permission_error. If the provided *Value* does not match the type of the flag, a type_error is raised.

In addition to ISO, SWI-Prolog allows for user-defined Prolog flags. The type of the flag is determined from the initial value and cannot be changed afterwards. Defined types are boolean (if the initial value is one of false, true, on or off), atom if the initial value is any other atom, integer if the value is an integer that can be expressed as a 64-bit signed value. Any other initial value results in an untyped flag that can represent any valid Prolog term.

### 2.12 An overview of hook predicates

SWI-Prolog provides a large number of hooks, mainly to control handling messages, debugging, startup, shut-down, macro-expansion, etc. Below is a summary of all defined hooks with an indication of their portability.

- **portray/1**
  Hook into write_term/3 to alter the way terms are printed (ISO).

- **message hook/3**
  Hook into print_message/2 to alter the way system messages are printed (Quintus/SICStus).
• library_directory/1
  Hook into absolute_file_name/3 to define new library directories. (most Prolog system).

• file_search_path/2
  Hook into absolute_file_name/3 to define new search-paths (Quintus/SICStus).

• term_expansion/2
  Hook into load_files/2 to modify read terms before they are compiled (macro-processing) (most Prolog system).

• goal_expansion/2
  Same as term_expansion/2 for individual goals (SICStus).

• prolog_load_file/2
  Hook into load_files/2 to load other data-formats for Prolog sources from ‘non-file’ resources. The load_files/2 predicate is the ancestor of consult/1, use_module/1, etc.

• prolog_edit:locate/3
  Hook into edit/1 to locate objects (SWI).

• prolog_edit:edit_source/1
  Hook into edit/1 to call some internal editor (SWI).

• prolog_edit:edit_command/2
  Hook into edit/1 to define the external editor to use (SWI).

• prolog_list_goal/1
  Hook into the tracer to list the code associated to a particular goal (SWI).

• prolog_trace_interception/4
  Hook into the tracer to handle trace-events (SWI).

• prolog:debug_control_hook/1
  Hook in spy/1, nospy/1, nospyall/0 and debugging/0 to extend these control-predicates to higher-level libraries.

• prolog:help_hook/1
  Hook in help/0, help/1 and apropos/1 to extend the help-system.

• resource/3
  Defines a new resource (not really a hook, but similar) (SWI).

• exception/3
  Old attempt to a generic hook mechanism. Handles undefined predicates (SWI).

• attr_unify_hook/2
  Unification hook for attributed variables. Can be defined in any module. See section 6.1 for details.
2.13 Automatic loading of libraries

If —at runtime— an undefined predicate is trapped the system will first try to import the predicate from the module’s default module. If this fails the auto loader is activated. On first activation an index to all library files in all library directories is loaded in core (see library_directory/1 and file_search_path/2). If the undefined predicate can be located in one of the libraries that library file is automatically loaded and the call to the (previously undefined) predicate is restarted. By default this mechanism loads the file silently. The current_prolog_flag/2 verbose_autoload is provided to get verbose loading. The Prolog flag autoload can be used to enable/disable the entire auto load system.

The auto-loader only works if the unknown flag (see unknown/2) is set to trace (default). A more appropriate interaction with this flag should be considered.

Autoloading only handles (library) source files that use the module mechanism described in chapter 5. The files are loaded with use_module/2 and only the trapped undefined predicate will be imported to the module where the undefined predicate was called. Each library directory must hold a file INDEX.pl that contains an index to all library files in the directory. This file consists of lines of the following format:

\[
\text{index(Name, Arity, Module, File)}.
\]

The predicate make/0 updates the autoload index. It searches for all library directories (see library_directory/1 and file_search_path/2) holding the file MKINDEX.pl or INDEX.pl. If the current user can write or create the file INDEX.pl and it does not exist or is older than the directory or one of its files, the index for this directory is updated. If the file MKINDEX.pl exists updating is achieved by loading this file, normally containing a directive calling make_library_index/2. Otherwise make_library_index/1 is called, creating an index for all *.pl files containing a module.

Below is an example creating a completely indexed library directory.

\[
\begin{align*}
\% & \text{mkdir } \sim/\text{lib/prolog} \\
\% & \text{cd } !$ \\
\% & \text{pl } -g \text{ true } -t \text{ make_library_index(.)}'
\end{align*}
\]

If there are more than one library files containing the desired predicate the following search schema is followed:

1. If there is a library file that defines the module in which the undefined predicate is trapped, this file is used.

2. Otherwise library files are considered in the order they appear in the library_directory/1 predicate and within the directory alphabetically.

\[
\begin{align*}
\text{make_library_index(} & +\text{Directory}) \\
\text{Create an index for this directory. The index is written to the file } & \text{INDEX.pl’ in the specified directory. Fails with a warning if the directory does not exist or is write protected.}
\end{align*}
\]

\[
\begin{align*}
\text{make_library_index(} & +\text{Directory, +ListOfPatterns}) \\
\text{Normally used in MKINDEX.pl, this predicate creates INDEX.pl for Directory, indexing all} & \text{files that match one of the file-patterns in ListOfPatterns.}
\end{align*}
\]
Sometimes library packages consist of one public load file and a number of files used by this load-file, exporting predicates that should not be used directly by the end-user. Such a library can be placed in a sub-directory of the library and the files containing public functionality can be added to the index of the library. As an example we give the XPCE library’s MKINDEX.pl, including the public functionality of trace/browse.pl to the autoloadable predicates for the XPCE package.

```prolog
:- make_library_index('.',
    ['*.pl',
     'trace/browse.pl'],
  ).
```

**reload_library_index**

Force reloading the index after modifying the set of library directories by changing the rules for library_directory/1, file_search_path/2, adding or deleting INDEX.pl files. This predicate does not update the INDEX.pl files. Check make_library_index/[1,2] and make/0 for updating the index files.

Normally, the index is reloaded automatically if a predicate cannot be found in the index and the set of library directories has changed. Using reload_library_index/0 is necessary if directories are removed or the order of the library directories is changed.

### 2.14 Garbage Collection

SWI-Prolog provides garbage-collection, last-call optimization and atom garbage collection. These features are controlled using Prolog flags (see current_prolog_flag/2).

### 2.15 Syntax Notes

SWI-Prolog uses ISO-Prolog standard syntax, which is closely compatible to Edinburgh Prolog syntax. A description of this syntax can be found in the Prolog books referenced in the introduction. Below are some non-standard or non-common constructs that are accepted by SWI-Prolog:

- */ . . .*/ . . .*/ . . .*/

  The /* . . . */ comment statement can be nested. This is useful if some code with /* . . . */ comment statements in it should be commented out.

#### 2.15.1 ISO Syntax Support

SWI-Prolog offers ISO compatible extensions to the Edinburgh syntax.

**Processor Character Set**

The processor character set specifies the class of each character used for parsing Prolog source text. Character classification is fixed to use UCS/Unicode as provided by the C-library wchar_t based primitives. See also section 2.17.
2.15. SYNTAX NOTES

Character Escape Syntax

Within quoted atoms (using single quotes: ‘<atom>’ special characters are represented using escape-sequences. An escape sequence is lead in by the backslash (\) character. The list of escape sequences is compatible with the ISO standard, but contains one extension and the interpretation of numerically specified characters is slightly more flexible to improve compatibility.

\a
Alert character. Normally the ASCII character 7 (beep).

\b
Backspace character.

\c
No output. All input characters up to but not including the first non-layout character are skipped. This allows for the specification of pretty-looking long lines. For compatibility with Quintus Prolog. Not supported by ISO. Example:

```
format('This is a long line that would look better if it was \c split across multiple physical lines in the input')
```

\RETURN
No output. Skips input till the next non-layout character or to the end of the next line. Same intention as \c but ISO compatible.

\f
Form-feed character.

\n
Next-line character.

\r
Carriage-return only (i.e. go back to the start of the line).

\t
Horizontal tab-character.

\v
Vertical tab-character (ASCII 11).

\xXX...
Hexadecimal specification of a character. The closing \ is obligatory according to the ISO standard, but optional in SWI-Prolog to enhance compatibility to the older Edinburgh standard. The code \xa\3 emits the character 10 (hexadecimal ‘a’) followed by ‘3’. Characters specified this way are interpreted as Unicode characters. See also \u.

\uXXXX
Unicode character specification where the character is specified using exactly 4 hexadecimal digits. This is an extension to the ISO standard fixing two problems. First of all, where \x defines a numeric character code, it doesn’t specify the character set in which the character should be interpreted. Second, it is not needed to use the idiosyncratic closing \ ISO Prolog syntax.
Same as \uXXXX, but using 8 digits to cover the whole Unicode set.

Octal character specification. The rules and remarks for hexadecimal specifications apply to octal specifications as well.

Any character immediately preceded by a \ and not covered by the above escape sequences is copied verbatim. Thus, ‘\\’ is an atom consisting of a single \ and ‘‘’’ and ‘’’’ both describe the atom with a single ‘’.

Character escaping is only available if the current_prolog_flag(character_escapes, true) is active (default). See current_prolog_flag/2. Character escapes conflict with writef/2 in two ways: \40 is interpreted as decimal 40 by writef/2, but character escapes handling by read has already interpreted as 32 (40 octal). Also, \l is translated to a single ‘l’. It is advised to use the more widely supported format/[2,3] predicate instead. If you insist upon using writef/2, either switch character_escapes to false, or use double \\, as in writef(‘\\l’).

Syntax for non-decimal numbers

SWI-Prolog implements both Edinburgh and ISO representations for non-decimal numbers. According to Edinburgh syntax, such numbers are written as ⟨radix⟩<number>, where ⟨radix⟩ is a number between 2 and 36. ISO defines binary, octal and hexadecimal numbers using 0[bx]⟨number⟩. For example: A is 0b100 \ 0xf00 is a valid expression. Such numbers are always unsigned.

Unicode Prolog source

The ISO standard specifies the Prolog syntax in ASCII characters. As SWI-Prolog supports Unicode in source files we must extend the syntax. This section describes the implication for the source files, while writing international source files is described in section 3.1.3.

The SWI-Prolog Unicode character classification is based on version 4.1.0 of the Unicode standard. Please note that char_type/2 and friends, intended to be used with all text except Prolog source code is based on the C-library locale-based classification routines.

- Quoted atoms and strings
  Any character of any script can be used in quoted atoms and strings. The escape sequences \uXXXX and \UXXXXXXXX (see section 2.15.1) were introduced to specify Unicode code points in ASCII files.

- Atoms and Variables
  We handle them in one item as they are closely related. The Unicode standard defines a syntax for identifiers in computer languages. In this syntax identifiers start with ID_Start followed by a sequence of ID_Continue codes. Such sequences are handled as a single token in SWI-Prolog. The token is a variable iff it starts with an uppercase character or an underscore (_). Otherwise it is an atom. Note that many languages do not have the notion of character-case. In such languages variables must be written as _name.
2.15. SYNTAX NOTES

- **White space**
  All characters marked as separators in the Unicode tables are handled as layout characters.

- **Other characters**
  The first 128 characters follow the ISO Prolog standard. All other characters not covered by the rules above are considered ‘solo’ characters: they form single-character atoms. We would like to have a more appropriate distinction between what is known to Prolog as ‘solo’ characters and ‘symbol’ characters.

**Singleton variable checking**

A *singleton variable* is a variable that appears only one time in a clause. It can always be replaced by _, the *anonymous* variable. In some cases however people prefer to give the variable a name. As mistyping a variable is a common mistake, Prolog systems generally give a warning (controlled by style_check/1) if a variable is used only once. The system can be informed a variable is known to appear once by starting it with an underscore. E.g. _Name. Please note that any variable, except plain _ shares with variables of the same name. The term t(_{X}, _{X}) is equivalent to t(X, X), which is different from t(_, _).

As Unicode requires variables to start with an underscore in many languages this schema needs to be extended.\(^7\) First we define the two classes of named variables.

- **Named singleton variables**
  Named singletons start with a double underscore (__) or a single underscore followed by an uppercase letter. E.g. __var or _Var.

- **Normal variables**
  All other variables are ‘normal’ variables. Note this makes _var a normal variable.\(^8\)

Any normal variable appearing exactly ones in the clause and any named singleton variables appearing more than once are reported. Below are some examples with warnings in the right column. Singleton messages can be suppressed using the style_check/1 directive.

\(^7\)After a proposal by Richard O’Keefe.

\(^8\)Some Prolog dialects write variables this way.
2.16 Infinite trees (cyclic terms)

SWI-Prolog has limited support for infinite trees, also known as cyclic terms. Full support requires special code in all built-in predicates that require recursive exploration of a term. The current version supports cycles terms in the pure Prolog kernel including the garbage collector and in the following predicates: =../2, ==/2, =@=/2, =/2, @</2, @=@=/2, @>/2, \==/2, \@=/2, \=-/2, acyclic_term/1, bagof/3, compare/3, copy_term/2, cyclic_term/1, dif/2, duplicate_term/2, findall/3, ground/1, term_hash/2, numbervars/[3, 4], recorda/3, recordz/3, setof/3, term_variables/2, throw/1, when/2, write/1 (incomplete).

2.17 Wide character support

SWI-Prolog supports wide characters, characters with character codes above 255 that cannot be represented in a single byte. Universal Character Set (UCS) is the ISO/IEC 10646 standard that specifies a unique 31-bits unsigned integer for any character in any language. It is a superset of 16-bit Unicode, which in turn is a superset of ISO 8859-1 (ISO Latin-1), a superset of US-ASCII. UCS can handle strings holding characters from multiple languages and character classification (uppercase, lowercase, digit, etc.) and operations such as case-conversion are unambiguously defined.

For this reason SWI-Prolog has two representations for atoms and string objects (see section 4.23). If the text fits in ISO Latin-1, it is represented as an array of 8-bit characters. Otherwise the text is represented as an array of 32-bit numbers. This representational issue is completely transparent to the Prolog user. Users of the foreign language interface as described in section 9 sometimes need to be aware of these issues though.

Character coding comes into view when characters of strings need to be read from or written to file or when they have to be communicated to other software components using the foreign language interface. In this section we only deal with I/O through streams, which includes file I/O as well as I/O through network sockets.

2.17.1 Wide character encodings on streams

Although characters are uniquely coded using the UCS standard internally, streams and files are byte (8-bit) oriented and there are a variety of ways to represent the larger UCS codes in an 8-bit octet stream. The most popular one, especially in the context of the web, is UTF-8. Bytes 0 ... 127 represent simply the corresponding US-ASCII character, while bytes 128 ... 255 are used for multi-byte encoding of characters placed higher in the UCS space. Especially on MS-Windows the 16-bit Unicode standard, represented by pairs of bytes is also popular.

Prolog I/O streams have a property called encoding which specifies the used encoding that influence get_code/2 and put_code/2 as well as all the other text I/O predicates.

The default encoding for files is derived from the Prolog flag encoding, which is initialised from the environment. If the environment variable LANG ends in "UTF-8", this encoding is assumed. Otherwise the default is text and the translation is left to the wide-character functions of the C-library. The encoding can be specified explicitly in load_files/2 for loading Prolog source with an alternative encoding, open/4 when opening files or using set_stream/2 on any open stream. For Prolog source files we also provide the encoding/1 directive that can be

---

*The Prolog native UTF-8 mode is considerably faster than the generic mbrtowc() one.*
used to switch between encodings that are compatible to US-ASCII (ascii, iso_latin_1, utf8 and many locales). See also section 3.1.3 for writing Prolog files with non-US-ASCII characters and section 2.15.1 for syntax issues. For additional information and Unicode resources, please visit http://www.unicode.org/.

SWI-Prolog currently defines and supports the following encodings:

**octet**
Default encoding for binary streams. This causes the stream to be read and written fully untranslated.

**ascii**
7-bit encoding in 8-bit bytes. Equivalent to iso_latin_1, but generates errors and warnings on encountering values above 127.

**iso_latin_1**
8-bit encoding supporting many western languages. This causes the stream to be read and written fully untranslated.

**text**
C-library default locale encoding for text files. Files are read and written using the C-library functions mbtowc() and wcrtomb(). This may be the same as one of the other locales, notably it may be the same as iso_latin_1 for western languages and utf8 in a UTF-8 context.

**utf8**
Multi-byte encoding of full UCS, compatible to ascii. See above.

**unicode_be**
Unicode **Big Endian**. Reads input in pairs of bytes, most significant byte first. Can only represent 16-bit characters.

**unicode_le**
Unicode **Little Endian**. Reads input in pairs of bytes, least significant byte first. Can only represent 16-bit characters.

Note that not all encodings can represent all characters. This implies that writing text to a stream may cause errors because the stream cannot represent these characters. The behaviour of a stream on these errors can be controlled using set_stream/2. Initially the terminal stream write the characters using Prolog escape sequences while other streams generate an I/O exception.

**BOM: Byte Order Mark**
From section 2.17.1, you may have got the impression text-files are complicated. This section deals with a related topic, making live often easier for the user, but providing another worry to the programmer. **BOM** or **Byte Order Marker** is a technique for identifying Unicode text-files as well as the encoding they use. Such files start with the Unicode character 0xFEFF, a non-breaking, zero-width space character. This is a pretty unique sequence that is not likely to be the start of a non-Unicode file and uniquely distinguishes the various Unicode file formats. As it is a zero-width blank, it even doesn’t produce any output. This solves all problems, or . . .

Some formats start of as US-ASCII and may contain some encoding mark to switch to UTF-8, such as the encoding="UTF-8" in an XML header. Such formats often explicitly forbid the use
of a UTF-8 BOM. In other cases there is additional information telling the encoding making the use of a BOM redundant or even illegal.

The BOM is handled by SWI-Prolog open/4 predicate. By default, text-files are probed for the BOM when opened for reading. If a BOM is found, the encoding is set accordingly and the property bom(true) is available through stream_property/2. When opening a file for writing, writing a BOM can be requested using the option bom(true) with open/4.

2.18 System limits

2.18.1 Limits on memory areas

SWI-Prolog has a number of memory areas which are only enlarged to a certain limit. The default sizes for these areas should suffice for most applications, but big applications may require larger ones. They are modified by command-line options. The table below shows these areas. The first column gives the option name to modify the size of the area. The option character is immediately followed by a number and optionally by a k or m. With k or no unit indicator, the value is interpreted in Kbytes (1024 bytes), with m, the value is interpreted in Mbytes (1024 × 1024 bytes).

The local-, global- and trail-stack are limited to 128 Mbytes on 32 bit processors, or more generally to 2bits-per-long−5 bytes.

The PrologScript facility described in section 2.10.2 provides a mechanism for specifying options with the load-file. On Windows the default stack-sizes are controlled using the Windows registry on the key HKEY_CURRENT_USER\Software\SWI\Prolog using the names localSize, globalSize and trailSize. The value is a DWORD expressing the default stack size in Kbytes. A GUI for modifying these values is provided using the XPCE package. To use this, start the XPCE manual tools using manpce/0, after which you find Preferences in the File menu.

The heap

With the heap, we refer to the memory area used by malloc() and friends. SWI-Prolog uses the area to store atoms, functors, predicates and their clauses, records and other dynamic data. As of SWI-Prolog 2.8.5, no limits are imposed on the addresses returned by malloc() and friends.

On some machines, the runtime stacks described above are allocated using ‘sparse allocation’. Virtual space up to the limit is claimed at startup and committed and released while the area grows and shrinks. On Win32 platform this is realised using VirtualAlloc() and friends. On Unix systems this is realised using mmap().

2.18.2 Other Limits

Clauses The only limit on clauses is their arity (the number of arguments to the head), which is limited to 1024. Raising this limit is easy and relatively cheap, removing it is harder.

Atoms and Strings SWI-Prolog has no limits on the sizes of atoms and strings. read/1 and its derivatives however normally limit the number of newlines in an atom or string to 5 to improve error detection and recovery. This can be switched off with style_check/1.

The number of atoms is limited to 16777216 (16M) on 32-bit machines. On 64-bit machines this is virtually unlimited. See also section 9.6.2.
### Table 2.2: Memory areas

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Area name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-L</td>
<td>16M</td>
<td>local stack</td>
<td>The local stack is used to store the execution environments of procedure invocations. The space for an environment is reclaimed when it fails, exits without leaving choice points, the alternatives are cut off with the 1/0 predicate or no choice points have been created since the invocation and the last subclause is started (last call optimisation).</td>
</tr>
<tr>
<td>-G</td>
<td>32M</td>
<td>global stack</td>
<td>The global stack is used to store terms created during Prolog’s execution. Terms on this stack will be reclaimed by backtracking to a point before the term was created or by garbage collection (provided the term is no longer referenced).</td>
</tr>
<tr>
<td>-T</td>
<td>32M</td>
<td>trail stack</td>
<td>The trail stack is used to store assignments during execution. Entries on this stack remain alive until backtracking before the point of creation or the garbage collector determines they are not needed any longer.</td>
</tr>
<tr>
<td>-A</td>
<td>1M</td>
<td>argument stack</td>
<td>The argument stack is used to store one of the intermediate code interpreter’s registers. The amount of space needed on this stack is determined entirely by the depth in which terms are nested in the clauses that constitute the program. Overflow is most likely when using long strings in a clause. In addition, this stack is used by some built-in predicates to handle cyclic terms. Its default size limit is proportional to the global stack limit such that it will never overflow.</td>
</tr>
</tbody>
</table>
**Memory areas** On 32-bit hardware, SWI-Prolog data is packed in a 32-bit word, which contains both type and value information. The size of the various memory areas is limited to 128 Mb for each of the areas, except for the program heap, which is not limited. On 64-bit hardware there are no meaningful limits.

**Nesting of terms** Many build-in predicates process nested terms using recursive C functions. Too deeply nested terms generally cause a fatal crash. All these functions avoid recursion on the right-most argument and therefore terms are not limited on the nesting level of the last argument. This notably covers long lists. Most functions use a stack for correct handling of rational trees (cyclic terms). This stack is segmented, where different segments are allocated using malloc(). Overflow causes a non-graceful exit.

**Integers** On most systems SWI-Prolog is compiled with support for unbounded integers by means of the GNU GMP library. In practice this means that integers are bound by the global stack size. Too large integers cause a resource_error. On systems that lack GMP, integers are 64-bit on 32 as well as 64-bit machines.

Integers up to the value of the max_tagged_integer Prolog flag are represented more efficiently on the stack. For clauses and records the difference is much smaller.

**Floating point numbers** Floating point numbers are represented as C-native double precision floats, 64 bit IEEE on most machines.

### 2.18.3 Reserved Names

The boot compiler (see -b option) does not support the module system. As large parts of the system are written in Prolog itself we need some way to avoid name clashes with the user’s predicates, database keys, etc. Like Edinburgh C-Prolog [Pereira, 1986] all predicates, database keys, etc. that should be hidden from the user start with a dollar ($) sign (see style_check/1).

### 2.19 SWI-Prolog and 64-bit machines

SWI-Prolog support for 64-bit machines started with version 2.8 on DEC Alpha CPUs running Linux. Initially 64-bit hardware was developed to deal with the addressing demands of large databases, running primarily on expensive server hardware. Recently (2007) we see CPUs that support 64-bit addressing become commonplace, even in low-budget desktop hardware. Most todays 64-bit platforms are capable of running both 32-bit and 64-bit applications. This asks for some clarifications on the advantages and drawbacks of 64-bit addressing for (SWI-)Prolog.

### 2.19.1 Supported platforms

On Unix systems, 64-bit addressing is configured using configure. Traditionally, both long and void* are 64-bits on these machines. Version 5.6.26 introduces support for 64-bit MS-Windows (Windows XP and Vista 64-bit editions) on amd64 (x64) hardware. Win64 uses long integers of only 32-bits. Version 5.6.26 introduces support for such platforms.

---

10With 64-bit machines we refer to CPUs where memory-addresses (pointers) are 64-bits wide.
2.19. SWI-PROLOG AND 64-BIT MACHINES

2.19.2 Comparing 32- and 64-bits Prolog

Most of Prolog’s memory-usage consists of pointers. This indicates the primary drawback: Prolog memory usage almost doubles when using the 64 bit addressing model. Using more memory means copying more data between CPU and main memory, slowing down the system.

What than are the advantages? First of all, SWI-Prolog’s addressing of the Prolog stacks does not cover the whole address space due to the use of type tag bits and garbage collection flags. On 32-bit hardware the stacks are limited to 128MB each. This tends to be too low for demanding applications on modern hardware. On 64-bit hardware the limit is $2^{32}$ times higher, exceeding the addressing capabilities of todays CPUs and operating systems. This implies Prolog can be started with stacks sizes that use the full capabilities of your hardware.

Multi-threaded applications profit much more. SWI-Prolog threads claim the full stacksize limit in virtual address space and each thread comes with its own set of stacks. This approach quickly exhaust virtual memory on 32-bit systems but poses no problems when using 64-bit addresses.

The implications theoretical performance loss due to increased memory bandwidth implied by exchanging wider pointers depend on the design of the hardware. We only have data for the popular IA32 vs. AMD64 architectures. Here is appears that the loss is compensated for by a an instruction set that has been optimized for modern programming. In particular, the AMD64 has more registers and the relative addressing capabilities have been improved. Where we see a 10% performance degradation when placing the SWI-Prolog kernel in a Unix shared object, we cannot find a measurable difference on AMD64. Current SWI-Prolog (5.6.26) runs at practically the same speed on IA32 and AMD64.

2.19.3 Choosing between 32- and 64-bits Prolog

For those cases where we can choose between 32- and 64-bits, either because the hardware and OS support both or because we can still choose the hardware and OS, we give guidelines for this decision.

First of all, if SWI-Prolog needs to be linked against 32- or 64-bit native libraries, there is no choice as it is not possible to link 32- and 64-bit code into a single executable. Only if all required libraries are available in both sizes and there is no clear reason to use either the different characteristics of Prolog become important.

Prolog applications that require more than the 128MB stack limit provided in 32-bit addressing mode must use the 64-bit edition. Note however that the limits must be doubled to accommodate the same Prolog application.

If the system is tight on physical memory, 32-bit Prolog has the clear advantage to use only slightly more than half of the memory of 64-bit Prolog. This argument applies as long as the application fits in the virtual address space of the machine. The virtual address space of 32-bit hardware is 4GB, but in many cases the operating system provides less to user applications. Virtual memory usage of SWI-Prolog is roughly the program size (heap) plus the sum of the stack-limits. If there are multiple threads, each thread has its own stacks and the stack-limits must be summed over the running threads.

The only standard SWI-Prolog library adding significantly to this calculation is the RDF database provided by the semweb package. It uses approximately 80 bytes per triple on 32-bit hardware and 150 bytes on 64-bit hardware. Details depend on how many different resources and literals appear in the dataset as well as desired additional literal indexes.

Summarizing, if applications are small enough to fit comfortably in virtual and physical memory simply take the model used by most of the applications on the OS. If applications require more than 128MB per stack, use the 64-bit edition. If applications approach the size of physical memory, fit
in the 128MB stack limit and fit in virtual memory, the 32-bit version has clear advantages. For demanding applications on 64-bit hardware with more than about 6GB physical memory the 64-bit model is the model of choice.
Initialising and Managing a Prolog Project

Prolog text-books give you an overview of the Prolog language. The manual tells you what predicates are provided in the system and what they do. This chapter wants to explain how to run a project. There is no ultimate ‘right’ way to do this. Over the years we developed some practice in this area and SWI-Prolog’s commands are there to support this practice. This chapter describes the conventions and supporting commands.

The first two sections (section 3.1 and section 3.2 only require plain Prolog. The remainder discusses the use of the built-in graphical tools that require the XPCE graphical library installed on your system.

3.1 The project source-files

Organisation of source-files depends largely on the size of your project. If you are doing exercises for a Prolog course you’ll normally use one file for each exercise. If you have a small project you’ll work with one directory holding a couple of files and some files to link it all together. Even bigger projects will be organised in sub-projects each using their own directory.

3.1.1 File Names and Locations

File Name Extensions

The first consideration is what extension to use for the source-files. Tradition calls for .pl, but conflicts with Perl force the use of another extension on systems where extensions have global meaning, such as MS-Windows. On such systems .pro is the common alternative.1

All versions of SWI-Prolog load files with the extension .pl as well as with the registered alternative extension without explicitly specifying the extension. For portability reasons we propose the following convention:

If there is no conflict because you do not use a conflicting application or the system does not force a unique relation between extension and application, use .pl.

With a conflict choose .pro and use this extension for the files you want to load through your file-manager. Use .pl for all other files for maximal portability.

Project Directories

Large projects are generally composed of sub-projects, each using their own directory or directory-structure. If nobody else will ever touch your files and you use only one computer there is little to

---

1On MS-Windows, the alternative extension is stored in the registry-key HKEY_CURRENT_USER/Software/SWI/Prolog/fileExtension or HKEY_LOCAL_MACHINE/Software/SWI/Prolog/fileExtension.
worry about, but this is rarely the case with a large project.

To improve portability, SWI-Prolog uses the POSIX notation for filenames, which uses the forward slash (/) to separate directories. Just before hitting the file-system it uses prolog_to_os_filename/2 to convert the filename to the conventions used by the hosting operating system. It is strongly advised to write paths using the /, especially on systems using the \ for this purpose (MS-Windows). Using \ violates the portability rules and requires you to double the \ due to the Prolog quoted-atom escape rules.

Portable code should use prolog_to_os_filename/2 to convert computed paths into system-paths when constructing commands for shell/1 and friends.

Sub-projects using search-paths

Thanks to Quintus, Prolog adapted an extensible mechanism for searching files using file_search_path/2. This mechanism allows for comfortable and readable specifications.

Suppose you have extensive library packages on graph-algorithms, set-operations and GUI-primitives. These sub-projects are likely candidates for re-use in future projects. A good choice is to create a directory with sub-directories for each of these sub-projects.

Next, there are three options. One is to add the sub-projects to the directory-hierarchy of the current project. Another is to use a completely dislocated directory and finally the sub-project can be added to the SWI-Prolog hierarchy. Using local installation, a typical file_search_path/2 is:

```prolog
:- prolog_load_context(directory, Dir),
   asserta(user:file_search_path(myapp, Dir)).

user:file_search_path(graph, myapp(graph)).
user:file_search_path(ui, myapp(ui)).
```

For using sub-projects in the SWI-Prolog hierarchy one should use the path-alias swi as basis. For a system-wide installation use an absolute-path.

Extensive sub-projects with a small well-defined API should define a load-file using use_module/1 calls to import the various library-components and export the API.

### 3.1.2 Project Special Files

There are a number of tasks you typically carry out on your project, such as loading it, creating a saved-state, debugging it, etc. Good practice on large projects is to define small files that hold the commands to execute such a task, name this file after the task and give it a file-extension that makes starting easy (see section 3.1.1). The task load is generally central to these tasks. Here is a tentative list.

- **load.pl**
  Use this file to set up the environment (Prolog flags and file search paths) and load the sources. Quite commonly this file also provides convenient predicates to parse command-line options and start the application.

- **run.pl**
  Use this file to start the application. Normally it loads load.pl in silent-mode, and calls one of the starting predicates from load.pl.
3.2. USING MODULES

- **save.pl**
  Use this file to create a saved-state of the application by loading load.pl and call qsave_program/2 to generate a saved-state with the proper options.

- **debug.pl**
  Loads the program for debugging. In addition to loading load.pl this file defines rules for portray/1 to modify printing rules for complex terms and customisation rules for the debugger and editing environment. It may start some of these tools.

3.1.3 International source files

As discussed in section 2.17, SWI-Prolog supports international character handling. Its internal encoding is UNICODE. I/O streams convert to/from this internal format. This sections discusses the options for source-files not in US-ASCII.

SWI-Prolog can read files in any of the encodings described in section 2.17. Two encodings are of particular interest. The text encoding deals with the current locale, the default used by this computer for representing text files. The encodings utf8, unicode_le and unicode_be are UNICODE encodings: they can represent—in the same file—characters of virtually any known language. In addition, they do so unambiguously.

If one wants to represent non US-ASCII text as Prolog terms in a source-file there are several options:

- **Use escape sequences**
  This approach describes NON-ASCII as sequences of the form \octal\. The numerical argument is interpreted as a UNICODE character.\footnote{To my knowledge, the ISO escape sequences is limited to 3 octal digits, which means most characters cannot be represented.} The resulting Prolog file is strict 7-bit US-ASCII, but if there are many NON-ASCII characters it becomes very unreadable.

- **Use local conventions**
  Alternatively the file may be specified using local conventions, such as the EUC encoding for Japanese text. The disadvantage is portability. If the file is moved to another machine this machine must be using the same locale or the file is unreadable. There is no elegant if files from multiple locales must be united in one application using this technique. In other words, it is fine for local projects in countries with uniform locale conventions.

- **Using UTF-8 files**
  The best way to specify source files with many NON-ASCII characters is definitely the use of UTF-8 encoding. Prolog can be notified two ways of this encoding, using a UTF-8 BOM (see section 2.17.1) or using the directive \:- encoding(utf8)\:. Many todays text editors, including PceEmacs, are capable of editing UTF-8 files. Projects that started using local conventions can be re-coded using the Unix iconv tool or often using a commands offered by the editor.

3.2 Using modules

Modules have been debated fiercely in the Prolog world. Despite all counter-arguments we feel they are extremely useful because
• They hide local predicates
  This is the reason they have been invented in the first place. Hiding provides two features. They allow for short predicate names without worrying about conflicts. Given the flat namespace introduced by modules, they still require meaningful module names as well as meaningful names for exported predicates.

• They document the interface
  Possibly more important then avoiding name-conflicts is their role in documenting which part of the file is for public usage and which is private. When editing a module you may assume you can reorganise anything but the name and semantics of the exported predicates without worrying.

• They help the editor
  The PceEmacs built-in editor does on-the-fly cross-referencing of the current module, colouring predicates based on their origin and usage. Using modules, the editor can quickly find out what is provided by the imported modules by reading just the first term. This allows it to indicate real-time which predicates are not used or not defined.

Using modules is generally easy. Only if you write meta-predicates (predicates reasoning about other predicates) that are exported from a module good understanding of resolution of terms to predicates inside a module is required. Here is a typical example from readutil.

```prolog
:- module(read_util,
  [ read_line_to_codes/2, % +Fd, -Codes
    read_line_to_codes/3, % +Fd, -Codes, ?Tail
    read_stream_to_codes/2, % +Fd, -Codes
    read_stream_to_codes/3, % +Fd, -Codes, ?Tail
    read_file_to_codes/3, % +File, -Codes, +Options
    read_file_to_terms/3 % +File, -Terms, +Options
  ]).
```

### 3.3 The test-edit-reload cycle

SWI-Prolog does not enforce the use of a particular editor for writing down Prolog source code. Editors are complicated programs that must be mastered in detail for real productive programming and if you are familiar with a specific editor you should not be forced to change. You may specify your favourite editor using the Prolog flag `editor`, the environment variable `EDITOR` or by defining rules for `prolog_edit:edit_source/1` (see section 4.4).

The use of a built-in editor, which is selected by setting the Prolog flag `editor` to `pce_emacs`, has advantages. The XPCE `editor` object around which the built-in PceEmacs is built can be opened as a Prolog stream allowing analysis of your source by the real Prolog system.

#### 3.3.1 Locating things to edit

The central predicate for editing something is `edit/1`, an extensible front-end that searches for objects (files, predicates, modules as well as XPCE classes and methods) in the Prolog database. If multiple matches are found it provides a choice. Together with the built-in completion on atoms bound to the `TAB` key this provides a quick way to edit objects:
3.4. USING THE PCEEMACS BUILT-IN EDITOR

?- edit(country).
Please select item to edit:

1 chat:country/10  '/staff/jan/lib/prolog/chat/countr.pl':16
2 chat:country/1   '/staff/jan/lib/prolog/chat/world0.pl':72

Your choice?

3.3.2 Editing and incremental compilation

One of the nice features of Prolog is that the code can be modified while the program is running. Using pure Prolog you can trace a program, find it is misbehaving, enter a break environment, modify the source code, reload it and finally do retry on the misbehaving predicate and try again. This sequence is not uncommon for long-running programs. For faster programs one normally aborts after understanding the misbehaviour, edit the source, reload it and try again.

One of the nice features of SWI-Prolog is the availability of make/0, a simple predicate that checks all loaded source files to see which ones you have modified. It then reloads these files, considering the module from which the file was loaded originally. This greatly simplifies the trace-edit-verify development cycle. After the tracer reveals there is something wrong with prove/3, you do:

?- edit(prove).

Now edit the source, possibly switching to other files and making multiple changes. After finishing invoke make/0, either through the editor UI (Compile/Make (Control-C Control-M)) or on the top-level and watch the files being reloaded.³

?- make.
% show compiled into photo_gallery 0.03 sec, 3,360 bytes

3.4 Using the PceEmacs built-in editor

3.4.1 Activating PceEmacs

Initially edit/1 uses the editor specified in the EDITOR environment variable. There are two ways to force it to use the built-in editor. One is to set the Prolog flag editor to pce_emacs and the other is by starting the editor explicitly using the emacs/[0,1] predicates.

3.4.2 Bluffing through PceEmacs

PceEmacs closely mimics Richard Stallman’s GNU-Emacs commands, adding features from modern window-based editors to make it more acceptable for beginners.⁴

³Watching these files is a good habit. If expected files are not reloaded you may have forgotten to save them from the editor or you may have been editing the wrong file (wrong directory).

⁴Decent merging with MS-Windows control-key conventions is difficult as many conflict with GNU-Emacs. Especially the cut/copy/paste commands conflict with important GNU-Emacs commands.
At the basis, PceEmacs maps keyboard sequences to methods defined on the extended editor object. Some frequently used commands are, with their key-binding, presented in the menu-bar above each editor window. A complete overview of the bindings for the current mode is provided through Help/Show key bindings (Control-h Control-b).

Edit modes

Modes are the heart of (Pce)Emacs. Modes define dedicated editing support for a particular kind of (source-)text. For our purpose we want Prolog mode. Their are various ways to make PceEmacs use Prolog mode for a file.

- **Using the proper extension**
  If the file ends in .pl or the selected alternative (e.g. .pro) extension, Prolog mode is selected.

- **Using #!/path/to/pl**
  If the file is a Prolog Script file, starting with the line #!/path/to/pl options -s, Prolog mode is selected regardless of the extension.

- **Using -*- Prolog -*-**
  If the above sequence appears in the first line of the file (inside a Prolog comment) Prolog mode is selected.

- **Explicit selection**
  Finally, using File/Mode/Prolog (y)ou can switch to Prolog mode explicitly.

Frequently used editor commands

Below we list a few important commands and how to activate them.

- **Cut/Copy/Paste**
  These commands follow Unix/X11 traditions. You’re best suited with a three-button mouse. After selecting using the left-mouse (double-click uses word-mode and triple line-mode), the selected text is automatically copied to the clipboard (X11 primary selection on Unix). Cut is achieved using the DEL key or by typing something else at the location. Paste is achieved using the middle-mouse (or wheel) button. If you don’t have a middle mouse-button, pressing the left- and right-button at the same time is interpreted as a middle-button click. If nothing helps there is the Edit/Paste menu-entry. Text is pasted at the caret-location.

- **Undo**
  Undo is bound to the GNU-Emacs Control-_ as well as the MS-Windows Control-Z sequence.

- **Abort**
  Multi-key sequences can be aborted at any stage using Control-G.

- **Find**
  Find (Search) is started using Control-S (forward) or Control-R (backward). PceEmacs implements incremental search. This is difficult to use for novices, but very powerful once you get the clue. After one of the above start-keys the system indicates search mode in the status line. As you are typing the search-string, the system searches for it, extending the search with every character you type. It illustrates the current match using a green background.
If the target cannot be found, PceEmacs warns you and no longer extends the search-string.\footnote{GNU-Emacs keeps extending the string, but why? Adding more text will not make it match.} During search some characters have special meaning. Typing anything but these characters commits the search, re-starting normal edit mode. Special commands are:

- **Control-S**
  - Search for next forwards.

- **Control-R**
  - Search for next backwards.

- **Control-W**
  - Extend search to next word-boundary.

- **Control-G**
  - Cancel search, go back to where it started.

- **ESC**
  - Commit search, leaving caret at found location.

- **Backspace**
  - Remove a character from the search string.

- **Dynamic Abbreviation**
  Also called *dabbrev* is an important feature of Emacs clones to support programming. After typing the first few letters of an identifier you may hit Alt-/, causing PceEmacs to search backwards for identifiers that start the same and using it to complete the text you typed. A second Alt-/ searches further backwards. If there are no hits before the caret it starts searching forwards. With some practice, this system allows for very fast entering code with nice and readable identifiers (or other difficult long words).

- **Open (a file)**
  Is called *File/Find file* (Control-x Control-f). By default the file is loaded into the current window. If you want to keep this window, Hit Alt-s or click the little icon at the bottom-left to make the window sticky.

- **Split view**
  Sometimes you want to look at two places of the same file. To do this, use Control-x 2 to create a new window pointing to the same file. Do not worry, you can edit as well as move around in both. Control-x 1 kills all other windows running on the same file.

These were the most commonly used commands. In section section 3.4.3 we discuss specific support for dealing with Prolog source code.

### 3.4.3 Prolog Mode

In the previous section (section 3.4.2) we explained the basics of PceEmacs. Here we continue with Prolog specific functionality. Possibly the most interesting is *Syntax highlighting*. Unlike most editors where this is based on simple patterns, PceEmacs syntax highlighting is achieved by Prolog itself actually reading and interpreting the source as you type it. There are three moments at which PceEmacs checks (part of) the syntax.
Table 3.1: Colour conventions

<tr>
<td>Comment</td>
</tr>
<tr>
<td>Quoted atom or string</td>
</tr>
<tr>
<td>Variable</td>
</tr>
</tbody>
</table>

- **After typing a `.`**
  After typing a `.`, that is not preceded by a *symbol* character the system assumes you completed a clause, tries to find the start of this clause and verifies the syntax. If this process succeeds it colours the elements of the clause according to the rules given below. Colouring is done using information from the last full check on this file. If it fails, the syntax error is displayed in the status line and the clause is not coloured.

- **After the command Control-c Control-s**
  Acronym for *C*heck *S*yntax it performs the same checks as above for the clause surrounding the caret. On a syntax error however, the caret is moved to the expected location of the error.6

- **After pausing for two seconds**
  After a short pause (2 seconds), PceEmacs opens the edit-buffer and reads it as a whole, creating an index of defined, called, dynamic, imported and exported predicates. After completing this, it re-reads the file and colours all clauses and calls with valid syntax.

- **After typing Control-l Control-l**
  The *Control-l* commands re-centers the window (scrolls the window to make the caret the center of the window). Hitting this command twice starts the same process as above.

**The colour schema** itself is defined in `emacs/prolog_colour`. The colouring can be extended and modified using multifile predicates. Please check this source-file for details. In general, underlined objects have a popup (right-mouse button) associated for common commands such as viewing the documentation or source. **Bold** text is used to indicate the definition of objects (typically predicates when using plain Prolog). Other colours follow intuitive conventions. See table 3.4.3.

**Layout support** Layout is not ‘just nice’, it is essential for writing readable code. There is much debate on the proper layout of Prolog. PceEmacs, being a rather small project supports only one particular style for layout.7 Below are examples of typical constructs.

---

6In most cases the location where the parser cannot proceed is further down the file than the actual error-location.

7Defined in Prolog in the file `emacs/prolog_mode`, you may wish to extend this. Please contribute your extensions!
head(arg1, arg2).

head(arg1, arg2) :- !.

head(Arg1, arg2) :- !,
call1(Arg1).

head(Arg1, arg2) :-
    ( if(Arg1)
    -> then
    ; else
    ).

head(Arg1) :-
    ( a
    ; b
    ).

head :-
a(many,
    long,
    arguments(with,
      many,
      more),
    and([ a,
      long,
      list,
      with,
      a,
      | tail
    ])).

PceEmacs uses the same conventions as GNU-Emacs. The TAB key indents the current line according to the syntax rules. Alt-q indents all lines of the current clause. It provides support for head, calls (indented 1 tab), if-then-else, disjunction and argument-lists broken across multiple lines as illustrated above.

Finding your way around

The command Alt-. extracts name and arity from the caret location and jumps (after confirmation or edit) to the definition of the predicate. It does so based on the source-location database of loaded predicates also used by edit/1. This makes locating predicates reliable if all sources are loaded and up-to-date (see make/0).

In addition, references to files in use_module/[1,2], consult/1, etc. are red if the file cannot be found and underlined blue if the file can be loaded. A popup allows for opening the referenced file.
3.5 The Graphical Debugger

SWI-Prolog offers two debuggers. One is the traditional text-console based 4-port Prolog tracer and the other is a window-based source-level debugger. The window-based debugger requires XPCE installed. It operates based on the `prolog_trace_interception/4` hook and other low-level functionality described in chapter B.

Window-based tracing provides much better overview due to the eminent relation to your source-code, a clear list of named variables and their bindings as well as a graphical overview of the call and choice-point stack. There are some drawbacks though. Using a textual trace on the console one can scroll back and examine the past, while the graphical debugger just presents a (much better) overview of the current state.

3.5.1 Invoking the window-based debugger

Whether the text-based or window-based debugger is used is controlled using the predicates `guitracer/0` and `noguitracer/0`. Entering debug mode is controlled using the normal predicates for this: `trace/0` and `spy/1`. In addition, PceEmacs prolog mode provides the command `Prolog/Break at (Control-c b)` to insert a break-point at a specific location in the source-code.

The graphical tracer is particulary useful for debugging threads. The tracer must be loaded from the main thread before it can be used from a background thread.

`guitracer`

This predicate installs the above-mentioned hooks that redirect tracing to the window-based environment. No window appears. The debugger window appears as actual tracing is started through `trace/0`, by hitting a spy-point defined by `spy/1` or a break-point defined using PceEmacs command `Prolog/Break at (Control-c b)`.

`noguitracer`

Disable the hooks installed by `guitracer/0`, reverting to normal text-console based tracing.

`gtrace`

Utility defined as `guitracer,trace`.

`gdebug`

Utility defined as `guitracer,debug`.

`gspy(+Predicate)`

Utility defined as `guitracer,spy(Predicate)`.

3.6 The Prolog Navigator

Another tool is the Prolog Navigator. This tool can be started from PceEmacs using the command `Browse/Prolog navigator`, from the GUI debugger or using the programmatic IDE interface described in section 3.8.
3.7  CROSS REFERENCER

A cross-referencers is a tool examining the caller-callee relation between predicates and using this information to explicate dependency relations between source files, find calls to non-existing predicates and predicates for which no callers can be found. Cross-referencing is useful during program development, reorganisation, cleanup, porting and other program maintenance tasks. The dynamic nature of Prolog makes the task non-trivial. Goals can be created dynamically call/1 after construction of a goal term. Abstract interpretation can find some of such calls, but the ultimately they can come from external communication, making it completely impossible to predict the callee. In other words, the cross-referencer has only partial understanding of the program and its results are necessarily incomplete. Still, it provides valuable information to the developer.

SWI-Prolog’s cross-referencer is split into two parts. The standard Prolog library prolog_xref is an extensible library for information gathering described in section A.18 and the XPCE library pce_xref provides a graphical frontend for the cross-referencer described here. We demonstrate the tool on CHAT80, a natural language question and answer system by Fernando C.N. Pereira and David H.D. Warren.

gxref

Run cross-referencer on all currently loaded files and present a graphical overview of the result.

As the predicate operates on the currently loaded application it must be run after loading the application.

The left window (see figure 3.1) provides browsers for loaded files and predicates. To avoid long file paths the file hierarchy has three main branches. The first is the current directory holding the sources. The second is marked alias and below it are the file-search-path aliases (see...
Figure 3.2: Dependencies between source files of CHAT80

file_search_path/2 and absolute_file_name/3). Here you find files loaded from the system as well as modules of the program loaded from other locations using file search path. All loaded files that fall outside these categories are below the last branch called /.

File where the system found suspicious dependencies are marked with an exclamation mark. This also holds for directories holding such files. Clicking on a file opens a File info window in the right pane.

The File info window shows a file, its main properties, its undefined and not-called predicates and its import- and export relations to other files in the project. Both predicates and files can be opened by clicking on them. The number of callers in a file for a certain predicate is indicated with a blue underlined number. A left-click will open a list and allows to edit the calling predicate.

The Dependencies (see figure 3.2) window displays a graphical overview of dependencies between files. Using the background menu a complete graph of the project can be created. It is also possible to drag files onto the graph window and use the menu on the nodes to incrementally expand the graph. The underlined blue text indicates the number of predicates used in the destination file. Left-clicking opens a menu to open the definition or select one of the callers.

Module and non-module files  The cross-referencer threads module and non-module project files differently. Module files have explicit import and export relations and the tool shows the usage and consistency of the relations. Using the menu-command Header the tool creates a consistent import list for the module that can be included in the file. The tool computes the dependency relations between the non-module files. If the user wishes to convert the project into a module-based one the Header command generates an appropriate module header and import list. Note that the cross-referencer may have missed dependencies and does not deal with meta-predicates defined in one module and called in another. Such problems must be resolved manually.

Settings  The following settings can be controlled from the settings menu:
Warn autoload
By default disabled. If enabled, modules that require predicates to be autoloaded are flagged with a warning and the file info window of a module shows the required autoload predicates.

Warn not called
If enabled (default), the file-overview shows an alert icon for files that have predicates that are not called.

3.8 Accessing the IDE from your program

Over the years a collection of IDE components have been developed, each with their own interface. In addition, some of these components require each other and loading IDE components must be on demand to avoid the IDE being part of a saved-state (see qsave_program/2). For this reason, access to the IDE will be concentrated on a single interface called prolog_ide/1:

\texttt{prolog_ide(+Action)}

This predicate ensures the IDE enabling XPCE component is loaded, creates the XPCE class \texttt{prolog_ide} and sends \texttt{Action} to its one and only instance \texttt{\index{@prolog_ide}\objectname{prolog_ide}}. \texttt{Action} is one of the following:

\texttt{open_navigator(+Directory)}
Open the Prolog Navigator (see section 3.6) in the given \texttt{Directory}.

\texttt{open_debug_status}
Open a window to edit spy- and trace-points.

\texttt{open_query_window}
Opens a little window to run Prolog queries from a GUI component.

\texttt{thread_monitor}
Open a graphical window indicating existing threads and their status.

\texttt{debug_monitor}
Open a graphical front-end for the \texttt{debug} library that provides an overview of the topics and catches messages.

\texttt{xref}
Open a graphical front-end for the cross-referencer that provides an overview of predicates and their callers.

3.9 Summary of the IDE

The SWI-Prolog development environment consists of a number of interrelated but not (yet) integrated tools. Here is a list of the most important features and tips.

- \textit{Atom completion}
  The console\textsuperscript{8} completes a partial atom on the TAB key and shows alternatives on the command Alt-?.

\textsuperscript{8}On Windows this is realised by plwin.exe, on Unix through the GNU readline library, which is included automatically when found by configure.
• **Use edit/1 to finding locations**
  The command `edit/1` takes the name of a file, module, predicate or other entity registered through extensions and starts the user's preferred editor at the right location.

• **Select editor**
  External editors are selected using the `EDITOR` environment variable, by setting the Prolog flag `editor` or by defining the hook `prolog_edit:edit_source/1`.

• **Update Prolog after editing**
  Using `make/0`, all files you have edited are re-loaded.

• **PceEmacs**
  Offers syntax-highlighting and checking based on real-time parsing of the editor's buffer, layout-support and navigation support.

• **Using the graphical debugger**
  The predicates `guitracer/0` and `noguitracer/0` switch between traditional text-based and window-based debugging. The tracer is activated using the `trace/0`, `spy/1` or menu-items from PceEmacs or the PrologNavigator.

• **The Prolog Navigator**
  Shows the file-structure and structure inside the file. It allows for loading files, editing, setting spy-points, etc.
4

Built-in predicates

4.1 Notation of Predicate Descriptions

We have tried to keep the predicate descriptions clear and concise. First the predicate name is printed in bold face, followed by the arguments in italics. Arguments are preceded by a mode indicator. There is no complete agreement on mode indicators in the Prolog community. We use the following definitions:\(^1\)

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Argument must be fully instantiated to a term that satisfies the required argument type. Think of the argument as input.</td>
</tr>
<tr>
<td>-</td>
<td>Argument must be unbound. Think of the argument as output.</td>
</tr>
<tr>
<td>?</td>
<td>Argument must be bound to a partial term of the indicated type. Note that a variable is a partial term for any type. Think of the argument as either input or output or both input and output. E.g. in <code>stream_property(S, reposition(Bool))</code>, the reposition part of the term is input and the uninstantiated <code>Bool</code> is output.</td>
</tr>
<tr>
<td>:</td>
<td>Argument is a meta-argument. Implies +. See section 5 for more information on module-handing.</td>
</tr>
<tr>
<td>@</td>
<td>Argument is not further instantiated. Typically used for type-tests.</td>
</tr>
<tr>
<td>!</td>
<td>Argument contains a mutable structure that may be modified using <code>setarg/3</code> or <code>nb_setarg/3</code>.</td>
</tr>
</tbody>
</table>

Referring to a predicate in running text is done using a predicate indicator. The canonical and most generic form of a predicate indicator is a term `<module>;<name>/(arity)`. If the module is irrelevant (built-in predicate) or can be inferred from the context it is often omitted. Compliant to the ISO standard draft on DCG (see section 4.12), SWI-Prolog also allows for `<module>;\langle name\rangle//\langle arity\rangle` to refer to a grammar rule. For all non-negative arity, `<name>//\langle arity\rangle` is the same as `<name>/(arity+2)\_\_\_\_\_\_` , regardless on whether or not the referenced predicate is defined or can be used as a grammar rule. The `//`-notation can be used in all places that traditionally allow for a predicate indicator, e.g. the module declaration, `spy/1`, and `dynamic/1`.

4.2 Character representation

In traditional (Edinburgh-) Prolog, characters are represented using character-codes. Character codes are integer indices into a specific character set. Traditionally the character set was 7-bits US-ASCII. 8-bit character sets have been allowed for a long time, providing support for national character sets.\(^1\)

---

\(^1\)These definitions are taken from PiDoc. The current manual has only one mode declaration per predicate and therefore predicates with mode (+,-) and (-,+) are described as (?,?). The @-mode is often replaced by +.
of which iso-latin-1 (ISO 8859-1) is applicable to many western languages. Text-files are supposed to
represent a sequence of character-codes.
ISO Prolog introduces three types, two of which are used for characters and one for accessing
binary streams (see open/4). These types are:

- **code**
  A character-code is an integer representing a single character. As files may use multi-byte
  encoding for supporting different character sets (utf-8 encoding for example), reading a code
  from a text-file in general not the same as reading a byte.

- **char**
  Alternatively, characters may be represented as one-character-atoms. This is a very natural rep-
  resentation, hiding encoding problems from the programmer as well as providing much easier
debugging.

- **byte**
  Bytes are used for accessing binary-streams.

The current version of SWI-Prolog does not provide support for multi-byte character encoding. This implies for example that it is not capable of breaking a multi-byte encoded atom into characters. For SWI-Prolog, bytes and codes are the same and one-character-atoms are simple atoms containing
one byte.

To ease the pain of these multiple representations, SWI-Prolog’s built-in predicates dealing with
character-data work as flexible as possible: they accept data in any of these formats as long as the
interpretation is unambiguous. In addition, for output arguments that are instantiated, the character
is extracted before unification. This implies that the following two calls are identical, both testing
whether the next input characters is an a.

```prolog
peek_code(Stream, a).
peek_code(Stream, 97).
```

These multiple-representations are handled by a large number of built-in predicates, all of which are
ISO-compatible. For converting between code and character there is char_code/2. For breaking
atoms and numbers into characters are are atom_chars/2, atom_codes/2, number_codes/2
and number_chars/2. For character I/O on streams there is get_char/[1,2],
get_code/[1,2], get_byte/[1,2], peek_char/[1,2], peek_code/[1,2],
peek_byte/[1,2], put_code/[1,2], put_char/[1,2] and put_byte/[1,2]. The
Prolog flag double_quotes controls how text between double-quotes is interpreted.

### 4.3 Loading Prolog source files

This section deals with loading Prolog source-files. A Prolog source file is a plain text file containing
a Prolog program or part thereof. Prolog source files come in three flavours:

- **A traditional** Prolog source file contains Prolog clauses and directives, but no module-declaration.
  They are normally loaded using consult/1 or ensure_loaded/1.
4.3. LOADING PROLOG SOURCE FILES

A **module**  Prolog source file starts with a module declaration. The subsequent Prolog code is loaded into the specified module and only the **public** predicates are made available to the context loading the module. Module files are normally loaded using `use_module([1,2])`. See chapter 5 for details.

An **include**  Prolog source file is loaded using the `include/1` directive and normally contains only directives.

Prolog source-files are located using `absolute_file_name/3` with the following options:

```
locate_prolog_file(Spec, Path) :-
    absolute_file_name(Spec, [ file_type(prolog),
                               access(read)
                           ], Path).
```

The `file_type(prolog)` option is used to determine the extension of the file using `prolog_file_type/2`. The default extension is `.pl`. `Spec` allows for the **path-alias** construct defined by `absolute_file_name/3`. The most commonly used path-alias is `library(LibraryFile)`. The example below loads the library file `ordsets.pl` (containing predicates for manipulating ordered sets).

```
:- use_module(library(ordsets)).
```

SWI-Prolog recognises grammar rules (DCG) as defined in [Clocksin & Melish, 1987]. The user may define additional compilation of the source file by defining the dynamic predicates `term_expansion/2` and `goal_expansion/2`. Transformations by `term_expansion/2` overrule the systems grammar rule transformations. It is not allowed to use `assert/1`, `retract/1` or any other database predicate in `term_expansion/2` other than for local computational purposes.

Directives may be placed anywhere in a source file, invoking any predicate. They are executed when encountered. If the directive fails, a warning is printed. Directives are specified by `:-/1` or `?-/1`. There is no difference between the two.

SWI-Prolog does not have a separate `reconsult/1` predicate. Reconsulting is implied automatically by the fact that a file is consulted which is already loaded.

**load_files**(+Files, +Options)

The predicate `load_files/2` is the parent of all the other loading predicates except for `include/1`. It currently supports a subset of the options of Quintus `load_files/2`. `Files` is either a single source-file, or a list of source-files. The specification for a source-file is handed to `absolute_file_name/2`. See this predicate for the supported expansions. `Options` is a list of options using the format

```
    OptionName(OptionValue)
```

The following options are currently supported:

---

2It does work for normal loading, but not for `qcompile/1`.
autoload(Bool)
If true (default false), indicate this load is a demand load. This implies that, depending on the setting of the Prolog flag verbose_autoload the load-action is printed at level informational or silent. See also print_message/2 and current_prolog_flag/2.

derived_from(File)
Indicate that the loaded file is derived from File. Used by make/0 to time-check and load the original file rather than the derived file.

encoding(Encoding)
Specify the way characters are encoded in the file. Default is taken from the Prolog flag encoding. See section 2.17.1 for details.

expand(Bool)
If true, run the filenames through expand_file_name/2 and load the returned files. Default is false, except for consult/1 which is intended for interactive use. Flexible location of files is defined by file_search_path/2.

format(+Format)
Used to specify the file format if data is loaded from a stream using the stream(Stream) option. Default is source, loading Prolog source text. If qlf, load QLF data (see qcompile/1).

if(Condition)
Load the file only if the specified condition is satisfied. The value true loads the file unconditionally, changed loads the file if it was not loaded before, or has been modified since it was loaded the last time, not_loaded loads the file if it was not loaded before.

imports(Import)
Specify what to import from the loaded module. The default for use_module/1 is all. Import is passed from the second argument of use_module/2. Traditionally it is a list of predicate indicators to import. As part of the SWI-Prolog/YAP integration, we also support Pred as Name to import a predicate under another name. Finally, Import can be a term except(Exceptions), where Exceptions is a list of predicate indicators that specify predicates that are not imported or Pred as Name terms to denote renamed predicates. See also reexport/2 and use_module/2.3

must_be_module(Bool)
If true, raise an error if the file is not a module file. Used by use_module/[1,2].

qcompile(Bool)
If this call appears in a directive of a file that is compiled into Quick Load Format using qcompile/1 and this flag is true, the contents of the argument files are included in the .qlf file instead of the loading directive.

reexport(Bool)
If true re-export the imported predicate. Used by reexport/1 and reexport/2.

silent(Bool)
If true, load the file without printing a message. The specified value is the default for all files loaded as a result of loading the specified files. This option writes the Prolog flag verbose_load with the negation of Bool.

---

3BUG: Name/Arity as NewName is currently implemented using a link clause. This harms efficiency and does not allow for querying the relation through predicate_property/2.
4.3. LOADING PROLOG SOURCE FILES

stream(Input)
This SWI-Prolog extension compiles the data from the stream Input. If this option is
used, Files must be a single atom which is used to identify the source-location of the
loaded clauses as well as remove all clauses if the data is re-consulted.
This option is added to allow compiling from non-file locations such as databases, the
web, the user (see consult/1) or other servers. It can be combined with format(qlf)
to load QLF data from a stream.

The load_files/2 predicate can be hooked to load other data or data from other objects than
files. See prolog_load_file/2 for a description and http_load for an example.

consult(+File)
Read File as a Prolog source file. File may be a list of files, in which case all members are
consulted in turn. File may start with the Unix shell special sequences ~, ⟨user⟩ and $⟨var⟩.
File may also be library(Name), in which case the libraries are searched for a file with
the specified name. See also library_directory/1 and file_search_path/2.
consult/1 may be abbreviated by just typing a number of file names in a list. Examples:

?- consult(load). % consult load or load.pl
?- [library(quintus)]. % load Quintus compatibility library
?- [user].

The predicate consult/1 is equivalent to load_files(Files, []), except for handling the spe-
cial file user, which reads clauses from the terminal. See also the stream(Input) option of
load_files/2.

ensure_loaded(+File)
If the file is not already loaded, this is equivalent to consult/1. Otherwise, if the file defines
a module, import all public predicates. Finally, if the file is already loaded, is not a module
file and the context module is not the global user module, ensure_loaded/1 will call
consult/1.

With the semantics, we hope to get as closely possible to the clear semantics without
the presence of a module system. Applications using modules should consider using
use_module/[1,2].
Equivalent to load_files(Files, [if(not_loaded)]).

include(+File)
Pretend the terms in File are in the source-file in which :- include(File) appears. The
include construct is only honoured if it appears as a directive in a source-file. Normally File
contains a sequence of directives.

require(+ListOfNameAndArity)
Declare that this file/module requires the specified predicates to be defined ”with their com-
monly accepted definition”. This predicate originates from the Prolog portability layer for

4On older versions the condition used to be if(changed). Poor time management on some machines or due to copying
often caused problems. The make/0 predicate deals with updating the running system after changing the source code.
XPCE. It is intended to provide a portable mechanism for specifying that this module requires the specified predicates.

The implementation normally first verifies whether the predicate is already defined. If not, it will search the libraries and load the required library.

SWI-Prolog, having autoloading, does not load the library. Instead it creates a procedure header for the predicate if it does not exist. This will flag the predicate as ‘undefined’. See also check/0 and autoload/0.

**encoding(\(+Encoding\)**

This directive can appear anywhere in a source file to define how characters are encoded in the remainder of the file. It can be used in files that are encoded with a superset of US-ASCII, currently UTF-8 and ISO Latin-1. See also section 2.17.1.

**make**

Consult all source files that have been changed since they were consulted. It checks all loaded source files: files loaded into a compiled state using `pl -c ...` and files loaded using consult or one of its derivatives. The predicate `make/0` is called after `edit/1`, automatically reloading all modified files. If the user uses an external editor (in a separate window), `make/0` is normally used to update the program after editing. In addition, `make/0` updates the autoload indices (see section 2.13) and runs `list_undefined/0` from the `check` library to report on undefined predicates.

**library_directory(?Atom)**

Dynamic predicate used to specify library directories. Default `.lib`, `~/.lib/prolog` and the system’s library (in this order) are defined. The user may add library directories using `assert/1`, `asserta/1` or remove system defaults using `retract/1`.

**file_search_path(+Alias, ?Path)**

Dynamic predicate used to specify ‘path-aliases’. This feature is best described using an example. Given the definition

```
user:file_search_path(library, X) :-
   library_directory(X).
user:file_search_path(swi, Home) :-
   current_prolog_flag(home, Home).
user:file_search_path(foreign, swi(ArchLib)) :-
   current_prolog_flag(arch, Arch),
   atom_concat('lib/', Arch, ArchLib).
user:file_search_path(foreign, swi(lib)).
```

the file specification `demo(myfile)` will be expanded to `/usr/lib/prolog/demo/myfile`. The second argument of `file_search_path/2` may be another alias.

Below is the initial definition of the file search path. This path implies `swi(\(Path\))` refers to a file in the SWI-Prolog home directory. The alias `foreign(\(Path\))` is intended for storing shared libraries (.so or .DLL files). See also `load_foreign_library/[1,2]`.

```
user:file_search_path(library, X) :-
   library_directory(X).
user:file_search_path(swi, Home) :-
   current_prolog_flag(home, Home).
user:file_search_path(foreign, swi(ArchLib)) :-
   current_prolog_flag(arch, Arch),
   atom_concat('lib/', Arch, ArchLib).
user:file_search_path(foreign, swi(lib)).
```
The file_search_path/2 expansion is used by all loading predicates as well as by absolute_file_name/[2,3].

The Prolog flag verbose_file_search can be set to true to help debugging Prolog’s search for files.

expand_file_search_path(+Spec, -Path)
Unifies Path with all possible expansions of the file name specification Spec. See also absolute_file_name/3.

prolog_file_type(?Extension, ?Type)
This dynamic multifile predicate defined in module user determines the extensions considered by file_search_path/2. Extension is the filename extension without the leading dot, Type denotes the type as used by the file_type(Type) option of file_search_path/2. Here is the initial definition of prolog_file_type/2:

```prolog
user:prolog_file_type(pl, prolog).
user:prolog_file_type(Ext, prolog) :-
    current_prolog_flag(associate, Ext),
    Ext \== pl.
user:prolog_file_type(qlf, qlf).
user:prolog_file_type(Ext, executable) :-
    current_prolog_flag(shared_object_extension, Ext).
```

Users may wish to change the extension used for Prolog source files to avoid conflicts (for example with perl) as well as to be compatible with some specific implementation. The preferred alternative extension is .pro.

source_file(?File)
True if File is a loaded Prolog source file. File is the absolute and canonical path to the source-file.

source_file(?Pred, ?File)
Is true if the predicate specified by Pred was loaded from file File, where File is an absolute path name (see absolute_file_name/2). Can be used with any instantiation pattern, but the database only maintains the source file for each predicate. See also clause_property/2.

prolog_load_context(?Key, ?Value)
Obtain context information during compilation. This predicate can be used from directives appearing in a source file to get information about the file being loaded. See also source_location/2. The following keys are defined:
<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>module</td>
<td>Module into which file is loaded</td>
</tr>
<tr>
<td>source</td>
<td>File loaded. Returns the original Prolog file when loading a .qlf file. Compatible to SICStus Prolog.</td>
</tr>
<tr>
<td>file</td>
<td>Currently equivalent to source. In future versions it may report a different values for files being loaded using include/1.</td>
</tr>
<tr>
<td>stream</td>
<td>Stream identifier (see current_input/1)</td>
</tr>
<tr>
<td>directory</td>
<td>Directory in which source lives.</td>
</tr>
<tr>
<td>dialect</td>
<td>Compatibility mode. See expects_dialect/1.</td>
</tr>
<tr>
<td>term_position</td>
<td>Position of last term read. Term of the form '$stream_position'(0,⟨Line⟩,0,0,0). See also stream_position_data/3.</td>
</tr>
</tbody>
</table>

**source_location(File, -Line)**

If the last term has been read from a physical file (i.e., not from the file user or a string), unify File with an absolute path to the file and Line with the line-number in the file. New code should use prolog_load_context/2.

**at_initialization(+Goal)**

Register Goal to be run when the system initialises. Initialisation takes place after reloading a .qlf (formerly .wic) file as well as after reloading a saved-state. The hooks are run in the order they were registered. A warning message is issued if Goal fails, but execution continues. See also at_halt/1

**at_halt(+Goal)**

Register Goal to be run from PL_cleanup(), which is called when the system halts. The hooks are run in the reverse order they were registered (FIFO). Success or failure executing a hook is ignored. If the hook raises an exception this is printed using print_message/2. An attempt to call halt/[0,1] from a hook is ignored.

**initialization(+Goal)**

Call Goal and register it using at_initialization/1. Directives that do other things than creating clauses, records, flags or setting predicate attributes should normally be written using this tag to ensure the initialisation is executed when a saved system starts. See also qsave_program/[1,2].

**compiling**

True if the system is compiling source files with the -c option or qcompile/1 into an intermediate code file. Can be used to perform conditional code optimisations in term_expansion/2 (see also the -O option) or to omit execution of directives during compilation.

### 4.3.1 Conditional compilation and program transformation

ISO Prolog defines no way for program transformations such as macro expansion or conditional compilation. Expansion through term_expansion/2 and expand_term/2 can be seen as part of the de-facto standard. This mechanism can do arbitrary translation between valid Prolog terms read from the source file to Prolog terms handed to the compiler. As term_expansion/2 can return a list, the transformation does not need to be term-to-term.
Various Prolog dialects provide the analogous `goal_expansion/2` and `expand_goal/2`, that allow for translation of individual body terms, freeing the user of the task to disassemble each clause.

**term_expansion(+Term1, -Term2)**

Dynamic and multifile predicate, normally not defined. When defined by the user all terms read during consulting are given to this predicate. If the predicate succeeds Prolog will assert `Term2` in the database rather than the read term (`Term1`). `Term2` may be a term of the form ‘?-Goal’ or ‘:-Goal’. Goal is then treated as a directive. If `Term2` is a list all terms of the list are stored in the database or called (for directives). If `Term2` is of the form below, the system will assert `Clause` and record the indicated source-location with it.

`'$source_location' (⟨File⟩, ⟨Line⟩) : ⟨Clause⟩`

When compiling a module (see chapter 5 and the directive `module/2`), `expand_term/2` will first try `term_expansion/2` in the module being compiled to allow for term-expansion rules that are local to a module. If there is no local definition, or the local definition fails to translate the term, `expand_term/2` will try `term_expansion/2` in module `user`. For compatibility with SICStus and Quintus Prolog, this feature should not be used. See also `expand_term/2, goal_expansion/2` and `expand_goal/2`.

**expand_term(+Term1, -Term2)**

This predicate is normally called by the compiler to perform preprocessing. First it calls `term_expansion/2`. If this predicate fails it performs a grammar-rule translation. If this fails it returns the first argument.

**goal_expansion(+Goal1, -Goal2)**

Like `term_expansion/2, goal_expansion/2` provides for macro-expansion of Prolog source-code. Between `expand_term/2` and the actual compilation, the body of clauses analysed and the goals are handed to `expand_goal/2`, which uses the `goal_expansion/2` hook to do user-defined expansion.

The predicate `goal_expansion/2` is first called in the module that is being compiled, and then on the `user` module. If `Goal` is of the form `Module:Goal` where `Module` is instantiated, `goal_expansion/2` is called on `Goal` using rules from module `Module` followed by `user`. Only goals appearing in the body of clauses when reading a source-file are expanded using this mechanism, and only if they appear literally in the clause, or as an argument to the meta-predicates `not/1, call/1, once/1, ignore/1, findall/3, bagof/3, setof/3` or `forall/2`. A real predicate definition is required to deal with dynamically constructed calls.

**expand_goal(+Goal1, -Goal2)**

This predicate is normally called by the compiler to perform preprocessing. First it calls `goal_expansion/2`. If this fails it returns the first argument.

**compile_aux_clauses(+Clauses)**

Compile clauses on behalf of `goal_expansion/2`. This predicate compiled the argument clauses into static predicates, associating the predicates with the current file but avoid changing the notion of current predicate and therefore discontinuous warnings.
preprocessor(-Old, +New)
Read the input file via an external process that acts as preprocessor. A preprocessor is specified as an atom. The first occurrence of the string ‘%f’ is replaced by the name of the file to be loaded. The standard output of resulting command is loaded. To use the Unix C preprocessor one should define:

?- preprocessor(Old, '/lib/cpp -C -P %f'), consult(...).
Old = none

Using cpp for Prolog preprocessing is not ideal as the tokenization rules for comment and quoted strings differ between C and Prolog. Another problem is availability and compatibility with regard to option processing of cpp.

Conditional compilation
Conditional compilation builds on the same principle as term_expansion/2, goal_expansion/2 and the expansion of grammar rules to compile sections of the source-code conditionally. One of the reasons for introducing conditional compilation is to simplify writing portable code. See section C for more information. Here is a simple example:

:- if(+source_exports(library(lists), suffix/2)).
suffix(Suffix, List) :-
append(_, Suffix, List).
:- endif.

Note that these directives can only appear as separate terms in the input. Typical usage scenarios include:

- Load different libraries on different dialects
- Define a predicate if it is missing as a system predicate
- Realise totally different implementations for a particular part of the code due to different capabilities.
- Realise different configuration options for your software.

:- if(:Goal)
Compile subsequent code only if Goal succeeds. For enhanced portability, Goal is processed by expand_goal/2 before execution. If an error occurs, the error is printed and processing proceeds as if Goal has failed.

:- elif(:Goal)
Equivalent to :- else. :-if(Goal) ... :- endif. In a sequence as below, the section below the first matching elif is processed, If no test succeeds the else branch is processed.
4.3. LOADING PROLOG SOURCE FILES

```prolog
:- if(test1).
section_1.
:- elif(test2).
section_2.
:- elif(test3).
section_3.
:- else.
section_else.
:- endif.

:- else
    Start ‘else’ branch.

:- endif
    End of conditional compilation.
```

4.3.2 Loading files, active code and threads

Traditionally, Prolog environments allow for reloading files holding currently active code. In particular, the following sequence is valid use of the development environment:

- Trace a goal
- Find unexpected behaviour of a predicate
- Enter a break using the b command
- Fix the sources and reload them using make/0
- Exit the break, retry using the r command

Goals running during the reload keep running on the old definition, while new goals use the reloaded definition, which is why the retry must be used after the reload. This implies that clauses of predicates that are active during the reload cannot be reclaimed. Normally a small amount of dead clauses should not be an issue during development. Such clauses can be reclaimed with garbage_collect_clauses/0.

**garbage_collect_clauses**

Cleanup all dirty predicates, where dirty predicates are defined to be predicates that have both old and new definitions due to reloading a source file while the predicate was active. Of course, predicates that are active using garbage_collect_clauses/0 cannot be reclaimed and remain dirty. Predicate are -like atoms- shared resources and therefore all threads are suspended during the execution of this predicate.

**Threads and reloading running code**

As of version 5.5.30, there is basic thread-safety for reloading source files while other threads are executing code defined in these source files. Reloading a file freezes all threads after marking the active predicates originating from the file being reloaded. The threads are resumed after
the file has been loaded. In addition, after completing loading the outermost file, the system runs 
garbage.collect.clauses/0.

What does that mean? Unfortunately it does not mean we can ‘hot-swap’ modules. Consider the 
case where thread $A$ is executing the recursive predicate $P$. We ‘fix’ $P$ and reload. The already run-
nning goals for $P$ continue to run the old definition, but new recursive calls will use the new definition!
Many similar cases can be constructed with dependent predicates.

It provides some basic security for reloading files in multi-threaded applications during develop-
ment. In the above scenarios the system does not crash uncontrolled, but behaves like any broken 
program: it may return the wrong bindings, wrong truth value or raise an exception.

Future versions may have an ‘update now’ facility. Such a facility can be implemented on top 
of the logical update view. It would allow threads to do a controlled update between processing 
independent jobs.

### 4.3.3 Quick load files

SWI-Prolog supports compilation of individual or multiple Prolog source files into ‘Quick Load Files’. 
A ‘Quick Load Files’ (.qlf file) stores the contents of the file in a precompiled format.

These files load considerably faster than source files and are normally more compact. They are 
machine independent and may thus be loaded on any implementation of SWI-Prolog. Note however 
that clauses are stored as virtual machine instructions. Changes to the compiler will generally make 
old compiled files unusable.

Quick Load Files are created using qcompile/1. They are loaded using consult/1 or one 
of the other file-loading predicates described in section 4.3. If consult is given the explicit .pl file, 
it will load the Prolog source. When given the .qlf file, it will load the file. When no extension is 
specified, it will load the .qlf file when present and the .pl file otherwise.

qcompile(+File)

Takes a single file specification like consult/1 (i.e., accepts constructs like 
library(LibFile) and, in addition to the normal compilation, creates a Quick Load File 
from File. The file-extension of this file is .qlf. The base name of the Quick Load File is the 
same as the input file.

If the file contains ‘:- consult(+File)’, ‘:- [+File]’ or 
:- load_files(+File, [qcompile(true), ...]) statements, the referred files are 
compiled into the same .qlf file. Other directives will be stored in the .qlf file and executed 
in the same fashion as when loading the .pl file.

For term.expansion/2, the same rules as described in section 2.10 apply.

Conditional execution or optimisation may test the predicate compiling/0.

Source references (source_file/2) in the Quick Load File refer to the Prolog source file 
from which the compiled code originates.

### 4.4 Listing and Editor Interface

SWI-Prolog offers an extensible interface which allows the user to edit objects of the program: predi-
cates, modules, files, etc. The editor interface is implemented by edit/1 and consists of three parts: 
locating, selecting and starting the editor.
4.4. LISTING AND EDITOR INTERFACE

Any of these parts may be extended or redefined by adding clauses to various multi-file (see multifile/1) predicates defined in the module prolog.edit.

The built-in edit specifications for edit/1 (see prolog.edit:locate/3) are described below.

<table>
<thead>
<tr>
<th>Fully specified objects</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="module(%E2%9F%A8Module%E2%9F%A9)" alt="Module!⟨Name⟩/⟨Arity⟩" /></td>
</tr>
<tr>
<td>Refers a predicate</td>
</tr>
<tr>
<td>![file(⟨Path⟩)]</td>
</tr>
<tr>
<td>Refers to a file</td>
</tr>
<tr>

</tr>
<tr>
<td>(2) a (source) file or (3) a module.</td>
</tr>
</tbody>
</table>

**edit(+Specification)**
First exploits prolog.edit:locate/3 to translate Specification into a list of Locations. If there is more than one ‘hit’, the user is asked to select from the locations found. Finally, prolog.edit:edit_source/1 is used to invoke the user’s preferred editor. Typically, edit/1 can be handed the name of a predicate, module, basename of a file, XPCE class, XPCE method, etc.

**edit**

Edit the ‘default’ file using edit/1. The default file is the file loaded with the command-line option -s or, in windows, the file loaded by double-clicking from the Windows shell.

**prolog.edit:locate(+Spec, -FullSpec, -Location)**

Where Spec is the specification provided through edit/1. This multi-file predicate is used to enumerate locations at with an object satisfying the given Spec can be found. FullSpec is unified with the complete specification for the object. This distinction is used to allow for ambiguous specifications. For example, if Spec is an atom, which appears as the base-name of a loaded file and as the name of a predicate, FullSpec will be bound to file(Path) or Name/Arity.

Location is a list of attributes of the location. Normally, this list will contain the term file(File) and —if available— the term line(Line).

**prolog.edit:locate(+Spec, -Location)**

Same as prolog.edit:locate/3, but only deals with fully-specified objects.

**prolog.edit:edit_source(+Location)**
Start editor on Location. See prolog.edit:locate/3 for the format of a location term. This multi-file predicate is normally not defined. If it succeeds, edit/1 assumes the editor is started.

If it fails, edit/1 uses its internal defaults, which are defined by the Prolog flag editor and/or the environment variable EDITOR. The following rules apply. If the Prolog flag editor is of the format $⟨name⟩, the editor is determined by the environment variable ⟨name⟩. Else, if this flag is pce_emacs or built_in and XPCE is loaded or can be loaded, the built-in Emacs clone is used. Else, if the environment EDITOR is set, this editor is used. Finally, vi is used as default on Unix systems and notepad on Windows.

See the default user preferences file dotfiles/dotplrc for examples.
**prolog_edit:edit_command(+Editor, -Command)**

Determines how Editor is to be invoked using shell/1. Editor is the determined editor (see edit_source/1), without the full path specification, and without possible (exe) extension. Command is an atom describing the command. The pattern %f is replaced by the full file-name of the location, and %d by the line number. If the editor can deal with starting at a specified line, two clauses should be provided, one holding only the %f pattern, and one holding both patterns.

The default contains definitions for vi, emacs, emacsclient, vim and notepad (latter without line-number version).

Please contribute your specifications to jan@swi.psy.uva.nl.

**prolog_edit:load**

Normally not-defined multifile predicate. This predicate may be defined to provide loading hooks for user-extensions to the edit module. For example, XPCE provides the code below to load swi_edit, containing definitions to locate classes and methods as well as to bind this package to the PceEmacs built-in editor.

```prolog
:- multifile prolog_edit:load/0.

prolog_edit:load :-
    ensure_loaded(library(swi_edit)).
```

**listing(+Pred)**

List specified predicates (when an atom is given all predicates with this name will be listed). The listing is produced on the basis of the internal representation, thus losing user’s layout and variable name information. See also portray_clause/1.

**listing**

List all predicates of the database using listing/1.

**portray_clause(+Clause)**

Pretty print a clause. A clause should be specified as a term ‘⟨Head⟩ :- ⟨Body⟩’. Facts are represented as ‘⟨Head⟩ :- true’ or simply ⟨Head⟩. Variables in the clause are written as A, B, . . .. Singleton variables are written as _ . See also portray_clause/2.

**portray_clause(+Stream, +Clause)**

Pretty print a clause to Stream. See portray_clause/1 for details.

### 4.5 Verify Type of a Term

**var(+Term)**

True if Term currently is a free variable.

**nonvar(+Term)**

True if Term currently is not a free variable.

**integer(+Term)**

True if Term is bound to an integer.
4.5. VERIFY TYPE OF A TERM

float(+Term)  [ISO]
True if Term is bound to a floating point number.

rational(+Term)
True if Term is bound to a rational number. Rational numbers include integers.

rational(+Term, -Numerator, -Denominator)
True if Term is bound to a rational number with given Numerator and Denominator. The Numerator and Denominator are in canonical form, which means Denominator is a positive integer and there are no common divisors between Numerator and Denominator.

number(+Term)  [ISO]
True if Term is bound to an integer or floating point number.  

atom(+Term)  [ISO]
True if Term is bound to an atom.

string(+Term)
True if Term is bound to a string. Note that string here refers to the built-in atomic type string as described in section 4.23. Text in double quotes such as "hello" creates a list of character codes. We illustrate the issues in the example queries below.

?- write("hello").
?- string("hello").
No
?- is_list("hello").
Yes

atomic(+Term)  [ISO]
True if Term is bound to an atom, string, integer or floating point number. Note that string refers to the built-in type. See string/1. Strings in the classical Prolog sense are lists and therefore compound.

compound(+Term)  [ISO]
True if Term is bound to a compound term. See also functor/3 and =../2.

callable(+Term)
True if Term is bound to an atom or a compound term, so it can be handed without type-error to call/1, functor/3 and =../2.

ground(+Term)
True if Term holds no free variables.

cyclic_term(+Term)
True if Term contains cycles, i.e. is an infinite term. See also acyclic_term/1 and section 2.16.  

5 As rational numbers are not atomic in the current implementation and we do not want to break the rule that number/1 implies atomic/1, number/1 fails on rational numbers. This will change if rational numbers become atomic.

6 The predicates cyclic_term/1 and acyclic_term/1 are compatible to SICStus Prolog. Some Prolog systems supporting cyclic terms use is_cyclic/1.
acyclic_term(+Term)
  True if Term does not contain cycles, i.e. can be processed recursively in finite time. See also cyclic_term/1 and section 2.16.

4.6 Comparison and Unification of Terms

Although unification is mostly done implicitly while matching the head of a predicate, it is also provided by the predicate =/2.

+Term1 = +Term2
  [ISO]
  Unify Term1 with Term2. True if the unification succeeds. For behaviour on cyclic terms see the Prolog flag occurs_check. It acts as if defined by the following rule.

= (Term, Term).

+Term1 \= +Term2
  [ISO]
  Equivalent to \+Term1 = Term2. See also dif/2.

4.6.1 Standard Order of Terms

Comparison and unification of arbitrary terms. Terms are ordered in the so called “standard order”. This order is defined as follows:

1. Variables < Numbers < Atoms < Strings < Compound Terms

2. Variables are sorted by address. Attaching attributes (see section 6.1) does not affect the ordering.

3. Atoms are compared alphabetically.

4. Strings are compared alphabetically.

5. Numbers are compared by value. Mixed integer/float are compared as floats. If the comparison is equal, the float is considered the smaller value. If the Prolog flag iso is defined, all floating point numbers precede all integers.

6. Compound terms are first checked on their arity, then on their functor-name (alphabetically) and finally recursively on their arguments, leftmost argument first.

+Term1 == +Term2
  [ISO]
  True if Term1 is equivalent to Term2. A variable is only identical to a sharing variable.

+Term1 \== +Term2
  [ISO]
  Equivalent to \+Term1 == Term2.

+Term1 @< +Term2
  [ISO]
  True if Term1 is before Term2 in the standard order of terms.

 Strings might be considered atoms in future versions. See also section 4.23
4.6. COMPARISON AND UNIFICATION OF TERMS

+Term1 @<= +Term2
True if both terms are equal (=/2) or Term1 is before Term2 in the standard order of terms.

+Term1 @> +Term2
True if Term1 is after Term2 in the standard order of terms.

+Term1 @>= +Term2
True if both terms are equal (=/2) or Term1 is after Term2 in the standard order of terms.

compare(?Order, +Term1, +Term2)
Determine or test the Order between two terms in the standard order of terms. Order is one of <, > or =, with the obvious meaning.

4.6.2 Special unification and comparison predicates

This section describes special purpose variations on Prolog unification. The predicate unify_with_occurs_check/2 provides sound unification and is part of the ISO standard. The predicates subsumes/2 and subsumes_chk/2 define ‘one-sided-unification’ and are found in many Prolog systems. Finally, unifiable/3 is a ‘what-if’ version of unification that is often used as a building block in constraint reasoners.

unify_with_occurs_check(+Term1, +Term2)
As =/2, but using sound-unification. That is, a variable only unifies to a term if this term does not contain the variable itself. To illustrate this, consider the two goals below:

1 ?- A = f(A).
A = f(f(f(f(f(f(f(f(f(f(...))))))))))
2 ?- unify_with_occurs_check(A, f(A)).
No

I.e. the first creates a cyclic-term, which is printed as an infinitely nested f/1 term (see the max_depth option of write_term/2). The second executes logically sound unification and thus fails. Note that the behaviour of unification through =/2 as well as implicit unification in the head can be changed using the Prolog flag occurs_check.

+Term1 @=+ +Term2
True if Term1 is ‘structurally equal’ to Term2. Structural equivalence is weaker than equivalence (=/2), but stronger than unification (=/2). Two terms are structurally equal if their tree representation is identical and they have the same ‘pattern’ of variables. Examples:

<table>
<thead>
<tr>
<th>Term1</th>
<th>Term2</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>A</td>
<td>false</td>
</tr>
<tr>
<td>A</td>
<td>B</td>
<td>true</td>
</tr>
<tr>
<td>x(A, A)</td>
<td>A</td>
<td>x(B, C)</td>
</tr>
<tr>
<td>x(A, A)</td>
<td>A</td>
<td>x(B, B)</td>
</tr>
<tr>
<td>x(A, B)</td>
<td>A</td>
<td>x(C, D)</td>
</tr>
</tbody>
</table>
The predicates \texttt{=@=/2} and \texttt{\textbackslash=@=/2} are cycle-safe. Attributed variables are considered structurally equal iff their attributes are structurally equal. This predicate is known by the name \texttt{variant/2} in some other Prolog systems.

\texttt{\texttt{+Term1 \textbackslash=@= +Term2}}

Equivalent to \texttt{\textbackslash++Term1 =@= Term2’}.

\textbf{subsumes(+Generic, @Specific)}

A term is told to \textit{subsume} another term if instantiation in the generic term produces the specific term. The subsumption relation is also called \textit{one sided unification} or \textit{semi-unification}. It behaves as if defined by\footnote{This implementation relies on the fact that \texttt{term_variables/2} orders its variables based on depth-first left-to-right traversal of the term.}

\begin{verbatim}
subsumes(General, Specific) :-
term_variables(Specific, SVars),
General = Specific,
term_variables(SVars, SVars2),
SVars == SVars2.
\end{verbatim}

\textbf{subsumes_chk(+Generic, @Specific)}

Equivalent to \texttt{\textbackslash++ \textbackslash++ subsumes(Generic, Specific)}.

\textbf{unifiable(@X, @Y, -Unifier)}

If \textit{X} and \textit{Y} can unify, unify \textit{Unifier} with a list of \textit{Var} = \textit{Value}, representing the bindings required to make \textit{X} and \textit{Y} equivalent.\footnote{This predicate was introduced for the implementation of \texttt{dif/2} and \texttt{when/2} after discussion with Tom Schrijvers and Bart Demoen. None of us is really happy with the name and therefore suggestions for a new name are welcome.} This predicate can handle cyclic terms. Attributed variables are handles as normal variables. Associated hooks are \textit{not} executed.

\textbf{?=(@Term1, @Term2)}

Decide whether the equality of \textit{Term1} and \textit{Term2} can be compared safely, i.e. whether the result of \texttt{Term1 == Term2} can change due to further instantiation of either term. It is defined as by \texttt{?=A,B} := \texttt{(A==B ; A \textbackslash= B)}, !. See also \texttt{dif/2}.

### 4.7 Control Predicates

The predicates of this section implement control structures. Normally the constructs in this section, except for \texttt{repeat/0}, are translated by the compiler. Please note that complex goals passed as arguments to meta-predicates such as \texttt{findall/3} below cause the goal to be compiled to a temporary location before execution. It is faster to define a sub-predicate (i.e. \texttt{one_character_atom/1} in the example below) and make a call to this simple predicate.

\begin{verbatim}
one_character_atoms(As) :-
    findall(A, (current_atom(A), atom_length(A, 1)), As).
\end{verbatim}
fail

Always fail. The predicate fail/0 is translated into a single virtual machine instruction.

false

Same as fail, but the name has a more declarative connotation.

ture

Always succeed. The predicate true/0 is translated into a single virtual machine instruction.

repeat

Always succeed, provide an infinite number of choice points.

! 

Cut. Discard choice points of parent frame and frames created after the parent frame. As of SWI-Prolog 3.3, the semantics of the cut are compliant with the ISO standard. This implies that the cut is transparent to ;/2, ->/2 and *->/2. Cuts appearing in the condition part of ->/2 and *->/2 as well as in \+/1 are local to the condition.\footnote{Up to version 4.0.6, the sequence X=!/0, X acted as a true cut. This feature has been deleted for ISO compliance.}

\[
\begin{align*}
t1 & :- (a, !, fail ; b). & \text{\% cuts a/0 and t1/0} \\
t2 & :- (a \rightarrow b, ! ; c). & \text{\% cuts b/0 and t2/0} \\
t3 & :- \text{call}((a, !, fail ; b)). & \text{\% cuts a/0} \\
t4 & :- \lor+(a, !, fail ; b). & \text{\% cuts a/0}
\end{align*}
\]

+Goal1 , +Goal2

Conjunction. True if both ‘Goal1’ and ‘Goal2’ can be proved. It is defined as (this definition does not lead to a loop as the second comma is handled by the compiler):

\[
\begin{align*}
\text{Goal1, Goal2} & :- \text{Goal1, Goal2.}
\end{align*}
\]

+Goal1 ; +Goal2

The ‘or’ predicate is defined as:

\[
\begin{align*}
\text{Goal1} ; \_\text{Goal2} & :- \text{Goal1.} \\
\_\text{Goal1} ; \text{Goal2} & :- \text{Goal2.}
\end{align*}
\]

+Goal1 | +Goal2

Equivalent to ;/2. Retained for compatibility only. New code should use ;/2.

+Condition -> +Action

If-then and If-Then-Else. The ->/2 construct commits to the choices made at its left-hand side, destroying choice-points created inside the clause (by ;/2), or by goals called by this clause. Unlike !/0, the choice-point of the predicate as a whole (due to multiple clauses) is not destroyed. The combination ;/2 and ->/2 acts as if defines by:

\[
\begin{align*}
\text{If -> Then; \_Else} & :- \text{If, !, Then.} \\
\text{If -> \_Then; \Else} & :- \!, \text{Else.} \\
\text{If -> Then} & :- \text{If, !, Then.}
\end{align*}
\]
Please note that (If \(\rightarrow\) Then) acts as (If \(\rightarrow\) Then ; fail), making the construct fail if the condition fails. This unusual semantics is part of the ISO and all de-facto Prolog standards.

\[+\text{Condition} \rightarrow +\text{Action} ; +\text{Else}\]

This construct implements the so-called ‘soft-cut’. The control is defined as follows: If Condition succeeds at least once, the semantics is the same as (Condition, Action). If Condition does not succeed, the semantics is that of (\(+\text{Condition}, \text{Else}\)). In other words, If Condition succeeds at least once, simply behave as the conjunction of Condition and Action, otherwise execute Else.

The construct A \(\rightarrow\) B, i.e. without an Else branch, is translated as the normal conjunction A, B.\[11\]

\[\neg +\text{Goal}\]

True if ‘Goal’ cannot be proven (mnemonic: + refers to provable and the backslash (\(\neg\)) is normally used to indicate negation in Prolog).

### 4.8 Meta-Call Predicates

Meta-call predicates are used to call terms constructed at run time. The basic meta-call mechanism offered by SWI-Prolog is to use variables as a subclause (which should of course be bound to a valid goal at runtime). A meta-call is slower than a normal call as it involves actually searching the database at runtime for the predicate, while for normal calls this search is done at compile time.

**call(+Goal)**

Invoke Goal as a goal. Note that clauses may have variables as subclauses, which is identical to call/1.

**call(+Goal, +ExtraArg1, \ldots)**

Append ExtraArg1, ExtraArg2, \ldots to the argument list of Goal and call the result. For example, call(plus(1), 2, X) will call plus/3, binding X to 3.

The call/[2..] construct is handled by the compiler, which implies that redefinition as a predicate has no effect. The predicates call/[2-6] are defined as true predicates, so they can be handled by interpreted code.

**apply(+Term, +List)**

Append the members of List to the arguments of Term and call the resulting term. For example: apply(plus(1), [2, X]) will call plus(1, 2, X). apply/2 is incorporated in the virtual machine of SWI-Prolog. This implies that the overhead can be compared to the overhead of call/1. New code should use call/[2..] if the length of List is fixed, which is more widely supported and faster because there is no need to build and examine the argument list.

**not(+Goal)**

True if Goal cannot be proven. Retained for compatibility only. New code should use \(\neg+/1\).

**once(+Goal)**

Defined as:

\[11\] BUG: The decompiler implemented by clause/2 returns this construct as a normal conjunction too.
4.8. META-CALL PREDICATES

\begin{verbatim}
once(Goal) :-
    Goal, !.
\end{verbatim}

once/1 can in many cases be replaced with \texttt{-}/2. The only difference is how the cut behaves (see \texttt{!}/0). The following two clauses are identical:

1) \texttt{a :- once((b, c)), d.}
2) \texttt{a :- b, c -> d.}

\textbf{ignore(+Goal)}

Calls \texttt{Goal} as \texttt{once/1}, but succeeds, regardless of whether \texttt{Goal} succeeded or not. Defined as:

\begin{verbatim}
negrate(Goal) :-
    Goal, !.
negrate(_).
\end{verbatim}

call\_with\_depth\_limit(+Goal, +Limit, -Result)

If \texttt{Goal} can be proven without recursion deeper than \texttt{Limit} levels, \texttt{call\_with\_depth\_limit/3} succeeds, binding \texttt{Result} to the deepest recursion level used during the proof. Otherwise, \texttt{Result} is unified with \texttt{depth\_limit\_exceeded} if the limit was exceeded during the proof, or the entire predicate fails if \texttt{Goal} fails without exceeding \texttt{Limit}.

The depth-limit is guarded by the internal machinery. This may differ from the depth computed based on a theoretical model. For example, \texttt{true/0} is translated into an inlined virtual machine instruction. Also, \texttt{repeat/0} is not implemented as below, but as a non-deterministic foreign predicate.

\begin{verbatim}
repeat.
repeat :-
    repeat.
\end{verbatim}

As a result, \texttt{call\_with\_depth\_limit/3} may still loop infinitely on programs that should theoretically finish in finite time. This problem can be cured by using Prolog equivalents to such built-in predicates.

This predicate may be used for theorem-provers to realise techniques like \textit{iterative deepening}. It was implemented after discussion with Steve Moyle smoyle@ermine.ox.ac.uk.

\textbf{call\_cleanup(:Goal, +Catcher, :Cleanup)}

Calls \texttt{Goal}. If \texttt{Goal} is completely finished, either by deterministic success, failure, its choice-point being cut or raising an exception and \texttt{Catcher} unifies to the termination code (see below), \texttt{Cleanup} is called. Success or failure of \texttt{Cleanup} is ignored and possible choice-points it created are destroyed (as \texttt{once/1}). If cleanup throws an exception this is executed as normal.\footnote{BUG: During the execution of \texttt{Cleanup}, garbage collection and stack-shifts are disabled.} \hfill 12

\texttt{Catcher} is unified with a term describing how the call has finished. If this unification fails, \texttt{Cleanup} is not called.
exit

{
  Goal succeeded without leaving any choice-points.
}

fail

{
  Goal failed.
}

!

{
  Goal succeeded with choice-points and these are now discarded by the execution of a cut
  (or other pruning of the search tree such as if-then-else).
}

exception(Exception)

{
  Goal raised the given Exception.
}

Typical use of this predicate is cleanup of permanent data storage required to execute Goal, close file-descriptors, etc. The example below provides a non-deterministic search for a term in a file, closing the stream as needed.

term_in_file(Term, File) :-
  open(File, read, In),
  call_cleanup(term_in_stream(Term, In), _, close(In)).

term_in_stream(Term, In) :-
  repeat,
  read(In, T),
  ( T == end_of_file
  -> !, fail
  ;  T = Term
  ).

Note that this predicate is impossible to implement in Prolog other than reading all terms into a list, close the file and call member/2 because without call_cleanup/3 there is no way to gain control if the choice-point left by repeat is killed by a cut.

The call_cleanup/2 can also be used to test determinism of a goal, providing a portable alternative to deterministic/1:

?- call_cleanup((X=1;X=2), Det=yes).

X = 1 ;

X = 2,
Det = yes ;

This predicate is a SWI-Prolog extension. See also call_cleanup/2 for compatibility to other Prolog implementations.

call_cleanup(:Goal, :Cleanup)

This predicate is equivalent to call_cleanup(Goal, _, Cleanup), calling Cleanup regardless of the reason for termination and without providing information. This predicate provides compatibility to a number of other Prolog implementations.
4.9 ISO COMPLIANT EXCEPTION HANDLING

setup_and_call_cleanup(:Setup, :Goal, :Cleanup)

This predicate is introduced to allow for the proper definition of predicates with temporary side-effects under asynchronous interrupts from call_with_time_limit/2 (package clib) or thread_signal/2. It behaves as if defined below, but the Cleanup handler is also called if the interrupt occurs between Setup and the call_cleanup/2 call.

setup_and_call_cleanup(Setup, Goal, Cleanup) :-
    Setup,
    call_cleanup(Goal, Cleanup).

4.9 ISO compliant Exception handling

SWI-Prolog defines the predicates catch/3 and throw/1 for ISO compliant raising and catching of exceptions. In the current implementation (4.0.6), most of the built-in predicates generate exceptions, but some obscure predicates merely print a message, start the debugger and fail, which was the normal behaviour before the introduction of exceptions.

catch(:Goal, +Catcher, :Recover) [ISO]

Behaves as call/1 if no exception is raised when executing Goal. If a exception is raised using throw/1 while Goal executes, and the Goal is the innermost goal for which Catcher unifies with the argument of throw/1, all choice-points generated by Goal are cut, the system backtracks to the start of catch/3 while preserving the thrown exception term and Recover is called as in call/1.

The overhead of calling a goal through catch/3 is very comparable to call/1. Recovery from an exception is much slower, especially if the exception-term is large due to the copying thereof.

throw(+Exception) [ISO]

Raise an exception. The system looks for the innermost catch/3 ancestor for which Exception unifies with the Catcher argument of the catch/3 call. See catch/3 for details.

ISO demands throw/1 to make a copy of Exception, walk up the stack to a catch/3 call, backtrack and try to unify the copy of Exception with Catcher. SWI-Prolog delays making a copy of Exception and backtracking until it actually found a matching catch/3 goal. The advantage is that we can start the debugger at the first possible location while preserving the entire exception context if there is no matching catch/3 goal. This approach can lead to different behaviour if Goal and Catcher of catch/3 call share variables. We assume this to be highly unlikely and could not think of a scenario where this is useful.13

If an exception is raised in a callback from C (see chapter 9) and not caught in the same callback, PL_next_solution() fails and the exception context can be retrieved using PL_exception().

4.9.1 Debugging and exceptions

Before the introduction of exceptions in SWI-Prolog a runtime error was handled by printing an error message, after which the predicate failed. If the Prolog flag debug_on_error was in effect (default),

13I’d like to acknowledge Bart Demeen for his clarifications on these matters.
the tracer was switched on. The combination of the error message and trace information is generally sufficient to locate the error.

With exception handling, things are different. A programmer may wish to trap an exception using catch/3 to avoid it reaching the user. If the exception is not handled by user-code, the interactive top-level will trap it to prevent termination.

If we do not take special precautions, the context information associated with an unexpected exception (i.e., a programming error) is lost. Therefore, if an exception is raised, which is not caught using catch/3 and the top-level is running, the error will be printed, and the system will enter trace mode.

If the system is in an non-interactive callback from foreign code and there is no catch/3 active in the current context, it cannot determine whether or not the exception will be caught by the external routine calling Prolog. It will then base its behaviour on the Prolog flag `debug_on_error`:

- `current_prolog_flag(debug_on_error, false)`
  The exception does not trap the debugger and is returned to the foreign routine calling Prolog, where it can be accessed using PL_exception(). This is the default.

- `current_prolog_flag(debug_on_error, true)`
  If the exception is not caught by Prolog in the current context, it will trap the tracer to help analysing the context of the error.

While looking for the context in which an exception takes place, it is advised to switch on `debug_mode` using the predicate `debug/0`. The hook `prolog_exception_hook/4` can be used to add more debugging facilities to exceptions. An example is the library `http/http_error`, generating a full stack trace on errors in the HTTP server library.

### 4.9.2 The exception term

Built-in predicates generates exceptions using a term `error(Formal, Context)`. The first argument is the ‘formal’ description of the error, specifying the class and generic defined context information. When applicable, the ISO error-term definition is used. The second part describes some additional context to help the programmer while debugging. In its most generic form this is a term of the form `context(Name/Arity, Message)`, where `Name/Arity` describes the built-in predicate that raised the error, and `Message` provides an additional description of the error. Any part of this structure may be a variable if no information was present.

### 4.9.3 Printing messages

The predicate `print_message/2` may be used to print a message term in a human readable format. The other predicates from this section allow the user to refine and extend the message system. The most common usage of `print_message/2` is to print error messages from exceptions. The code below prints errors encountered during the execution of `Goal`, without further propagating the exception and without starting the debugger.

```prolog
...,  
catch(Goal, E,  
    ( print_message(error, E),  
      fail
```
Another common use is to define `message_hook/3` for printing messages that are normally `silent`, suppressing messages, redirecting messages or make something happen in addition to printing the message.

**`print_message(+Kind, +Term)`**

The predicate `print_message/2` is used to print messages, notably from exceptions in a human-readable format. `Kind` is one of `informational`, `banner`, `warning`, `error`, `help` or `silent`. A human-readable message is printed to the stream `user_error`.

If the Prolog flag `verbose` is `silent`, messages with `Kind` `informational`, or `banner` are treated as `silent`. See `-q`.

This predicate first translates the `Term` into a list of ‘message lines’ (see `print_message_lines/3` for details). Next it will call the hook `message_hook/3` to allow the user intercepting the message. If `message_hook/3` fails it will print the message unless `Kind` is `silent`.

The `print_message/2` predicate and its rules are in the file `<plhome>/boot/messages.pl`, which may be inspected for more information on the error messages and related error terms. If you need to report errors from your own predicates, we advise you to stick to the existing error terms if you can; but should you need to invent new ones, you can define corresponding error messages by asserting clauses for `prolog:message`. You will need to declare the predicate as `multifile`.

See also `message_to_string/2`.

**`print_message_lines(+Stream, +Prefix, +Lines)`**

Print a message (see `print_message/2`) that has been translated to a list of message elements. The elements of this list are:

```
⟨Format⟩-⟨Args⟩
```

Where `Format` is an atom and `Args` is a list of format argument. Handed to `format/3`.

**flush**

If this appears as the last element, `Stream` is flushed (see `flush_output/1`) and no final newline is generated.

**at_same_line**

If this appears as first element, no prefix is printed for the first line and the line-position is not forced to 0 (see `format/1`, `'N`).

```
⟨Format⟩
```

Handed to `format/3` as `format(Stream, Format, [])`.

**nl**

A new line is started and if the message is not complete the `Prefix` is printed too.

See also `print_message/2` and `message_hook/3`. 
message_hook(+Term, +Kind, +Lines)

Hook predicate that may be defined in the module user to intercept messages from print_message/2. Term and Kind are the same as passed to print_message/2. Lines is a list of format statements as described with print_message_lines/3. See also message_to_string/2.

This predicate should be defined dynamic and multifile to allow other modules defining clauses for it too.

message_to_string(+Term, -String)

Translates a message-term into a string object (see section 4.23). Primarily intended to write messages to Windows in XPCE (see section 1.5) or other GUI environments.

4.10 Handling signals

As of version 3.1.0, SWI-Prolog is capable to handle software interrupts (signals) in Prolog as well as in foreign (C) code (see section 9.6.12).

Signals are used to handle internal errors (execution of a non-existing CPU instruction, arithmetic domain errors, illegal memory access, resource overflow, etc.), as well as for dealing asynchronous inter-process communication.

Signals are defined by the POSIX standard and part of all Unix machines. The MS-Windows Win32 provides a subset of the signal handling routines, lacking the vital functionality to raise a signal in another thread for achieving asynchronous inter-process (or inter-thread) communication (Unix kill() function).

on_signal(+Signal, -Old, :New)

Determines the reaction on Signal. Old is unified with the old behaviour, while the behaviour is switched to New. As with similar environment-control predicates, the current value is retrieved using on_signal(Signal, Current, Current).

The action description is an atom denoting the name of the predicate that will be called if Signal arrives. on_signal/3 is a meta-predicate, which implies that ⟨Module⟩:⟨Name⟩ refers the ⟨Name⟩/1 in the module ⟨Module⟩.

Two predicate-names have special meaning. throw implies Prolog will map the signal onto a Prolog exception as described in section 4.9. default resets the handler to the settings active before SWI-Prolog manipulated the handler.

Signals bound to a foreign function through PL_signal() are reported using the term $foreign_function(Address).

After receiving a signal mapped to throw, the exception raised has the structure

\[
\text{error(signal(⟨SigName⟩, ⟨SigNum⟩), ⟨Context⟩)}
\]

One possible usage of this is, for example, to limit the time spent on proving a goal. This requires a little C-code for setting the alarm timer (see chapter 9):

```
#include <SWI-Prolog.h>
#include <unistd.h>
```
4.10. HANDLING SIGNALS

```prolog
foreign_t
pl_alarm(term_t time)
{ double t;

  if ( PL_get_float(time, &t) )
  { alarm((long)(t+0.5));

     PL_succeed;
  }

  PL_fail;
}

install_t
install()
{ PL_register_foreign("alarm", 1, pl_alarm, 0);
}
```

Next, we can define the Prolog below. This will run `Goal` just as `once/1`, throwing the exception `error(signal(alrm, _, _))` if a timeout occurs.¹⁴

```prolog
:- load_foreign_library(alarm).
:- on_signal(alrm, _, throw).
:- module_transparent
    call_with_time_limit/2.

call_with_time_limit(MaxTime, Goal) :-
    alarm(MaxTime),
    call_cleanup(Goal, _, alarm(0)), !.
```

The signal names are defined by the POSIX standard as symbols of the form `SIG_⟨SIGNAME⟩`. The Prolog name for a signal is the lowercase version of `⟨SIGNAME⟩`. The predicate `current_signal/3` may be used to map between names and signals.

Initially, some signals are mapped to `throw`, while all other signals are `default`. The following signals throw an exception: `ill`, `fpe`, `segv`, `pipe`, `alrm`, `bus`, `xcpu`, `xfsz` and `vtalrm`.

```prolog
current_signal(?Name, ?Id, ?Handler)
```

Enumerate the currently defined signal handling. `Name` is the signal name, `Id` is the numerical identifier and `Handler` is the currently defined handler (see `on_signal/3`).

¹⁴Note that `call_with_time_limit/2` is defined in `time`, part of the `cib` package. The version provided in the library runs on POSIX systems as well as MS-Windows and can schedule multiple concurrent alarms.
4.10.1 Notes on signal handling

Before deciding to deal with signals in your application, please consider the following:

- **Portability**
  On MS-Windows, the signal interface is severely limited. Different Unix brands support different sets of signals, and the relation between signal name and number may vary.

- **Safety**
  Signal handling is not completely safe in the current implementation, especially if `throw` is used in combination with external foreign code. The system will use the C `longjmp()` construct to direct control to the innermost `PL_next_solution()`, thus forcing an external procedure to be abandoned at an arbitrary moment. Most likely not all SWI-Prolog’s own foreign code is (yet) safe too. For the multi-threaded versions this is even worse: signals can easily violate thread synchronisation consistency.

  The C-interface described in section 9.6.12 provides the option `PL_SIGSYNC` for registering a signal handler that delays delivery of signals to a safe point. Unfortunately this may cause signals to be delayed for a long time if Prolog is executing foreign code.

- **Garbage Collection**
  The garbage collector will block all signals that are handled by Prolog. While handling a signal, the garbage-collector is disabled.

- **Time of delivery**
  Normally delivery is immediate (or as defined by the operating system used). Signals are blocked when the garbage collector is active, and internally delayed if they occur within a ‘critical section’. The critical sections are generally very short.

4.11 The ‘block’ control-structure

The `block/3` predicate and friends have been introduced before ISO compatible `catch/3` exception handling for compatibility with some Prolog implementation. The only feature not covered by `catch/3` and `throw/1` is the possibility to execute global cuts. New code should use `catch/3` and `throw/1` to deal with exceptions.

`block(+Label, +Goal, -ExitValue)`

Execute `Goal` in a `block`. `Label` is the name of the block. `Label` is normally an atom, but the system imposes no type constraints and may even be a variable. `ExitValue` is normally unified to the second argument of an `exit/2` call invoked by `Goal`.

`exit(+Label, +Value)`

Calling `exit/2` makes the innermost `block` which `Label` unifies exit. The block’s `ExitValue` is unified with `Value`. If this unification fails the block fails.

`fail(+Label)`

Calling `fail/1` makes the innermost `block` which `Label` unifies fail immediately. Implemented as

```
fail(Label) :- !(Label), fail.
```
4.12. DCG Grammar rules

Grammar rules form a comfortable interface to difference-lists. They are designed both to support writing parsers that build a parse-tree from a list as for generating a flat list from a term. Unfortunately, Definite Clause Grammar (DCG) handling is not part of the Prolog standard. Most Prolog engines implement DCG, but the details differ slightly.

Grammar rules look like ordinary clauses using \(--\)/2 for separating the head and body rather than \(-\)/2. Expanding grammar rules is done by \texttt{expand_term/2}, which adds two additional argument to each term for representing the difference list. We will illustrate the behaviour by defining a rule-set for parsing an integer.

\begin{verbatim}
integer(I) \-->
digit(D0),
digits(D),
{ number_chars(I, [D0|D]) }

digits([D|T]) \-->
digit(D), !,
digits(T).
digits([]) \-->
[ ].
digit(D) \-->
[D],
{ code_type(D, digit) }
\end{verbatim}

The body of a grammar rule can contain three types of terms. A compound term interpreted as a reference to a grammar-rule. Code between \{ \ldots \} is interpreted as a reference to ordinary Prolog code and finally, a list is interpreted as a sequence of literals. The Prolog control-constructs (\+/1, \-->/2, ;//2, ,/2 and !/0) can be used in grammar rules.

Grammar rule-sets are called using the built-in predicates \texttt{phrase/2} and \texttt{phrase/3}:

\begin{verbatim}
phrase(+RuleSet, +InputList)
   Equivalent to \texttt{phrase(RuleSet, InputList, [])}.

phrase(+RuleSet, +InputList, -Rest)
   Activate the rule-set with given name. ‘InputList’ is the list of tokens to parse, ‘Rest’ is unified with the remaining tokens if the sentence is parsed correctly. The example below calls the rule-set ‘integer’ defined above.

?- phrase(integer(X), "42 times", Rest).
\end{verbatim}
4.13 Database

SWI-Prolog offers three different database mechanisms. The first one is the common assert/retract mechanism for manipulating the clause database. As facts and clauses asserted using `assert/1` or one of its derivatives become part of the program these predicates compile the term given to them. `retract/1` and `retractall/1` have to unify a term and therefore have to decompile the program. For these reasons the assert/retract mechanism is expensive. On the other hand, once compiled, queries to the database are faster than querying the recorded database discussed below. See also `dynamic/1`.

The second way of storing arbitrary terms in the database is using the “recorded database”. In this database terms are associated with a `key`. A key can be an atom, small integer or term. In the last case only the functor and arity determine the key. Each key has a chain of terms associated with it. New terms can be added either at the head or at the tail of this chain.

The third mechanism is a special purpose one. It associates an integer or atom with a key, which is an atom, integer or term. Each key can only have one atom or integer associated with it.

```
abolish(+PredicateIndicator)  [ISO]
Removes all clauses of a predicate with functor `Functor` and arity `Arity` from the database. All predicate attributes (dynamic, multifile, index, etc.) are reset to their defaults. Abolishing an imported predicate only removes the import link; the predicate will keep its old definition in its definition module.

According to the ISO standard, `abolish/1` can only be applied to dynamic procedures. This is odd, as for dealing with dynamic procedures there is already `retract/1` and `retractall/1`. The `abolish/1` predicate has been introduced in DEC-10 Prolog precisely for dealing with static procedures. In SWI-Prolog, `abolish/1` works on static procedures, unless the prolog flag `iso` is set to `true`.

It is advised to use `retractall/1` for erasing all clauses of a dynamic predicate.
```

```
abolish(+Name, +Arity)
Same as `abolish(Name/Arity)`. The predicate `abolish/2` conforms to the Edinburgh standard, while `abolish/1` is ISO compliant.
```

```
redefine_system_predicate(+Head)
This directive may be used both in module `user` and in normal modules to redefine any system predicate. If the system definition is redefined in module `user`, the new definition is the default definition for all sub-modules. Otherwise the redefinition is local to the module. The system definition remains in the module `system`.

Redefining system predicate facilitates the definition of compatibility packages. Use in other context is discouraged.
```

```
retract(+Term)  [ISO]
When `Term` is an atom or a term it is unified with the first unifying fact or clause in the database. The fact or clause is removed from the database.
```
4.13. DATABASE

retractall(+Head)
All facts or clauses in the database for which the head unifies with Head are removed.

assert(+Term)
Assert a fact or clause in the database. Term is asserted as the last fact or clause of the corresponding predicate.

asserta(+Term)  [ISO]
Equivalent to assert/1, but Term is asserted as first clause or fact of the predicate.

assertz(+Term)  [ISO]
Equivalent to assert/1.

assert(+Term, -Reference)
Equivalent to assert/1, but Reference is unified with a unique reference to the asserted clause. This key can later be used with clause/3 or erase/1.

asserta(+Term, -Reference)
Equivalent to assert/2, but Term is asserted as first clause or fact of the predicate.

assertz(+Term, -Reference)
Equivalent to assert/2.

recorda(+Key, +Term, -Reference)
Assert Term in the recorded database under key Key. Key is a small integer (range min_tagged_integer ... max_tagged_integer, atom or compound term. If the key is a compound term, only the name and arity define the key. Reference is unified with a unique reference to the record (see erase/1).

recorda(+Key, +Term)
Equivalent to recorda(Key, Value, _).

recordz(+Key, +Term, -Reference)
Equivalent to recorda/3, but puts the Term at the tail of the terms recorded under Key.

recordz(+Key, +Term)
Equivalent to recordz(Key, Value, _).

recorded(+Key, -Value, -Reference)
Unify Value with the first term recorded under Key which does unify. Reference is unified with the memory location of the record.

recorded(+Key, -Value)
Equivalent to recorded(Key, Value, _).

erase(+Reference)
Erase a record or clause from the database. Reference is an integer returned by recorda/3 or recorded/3, clause/3, assert/2, asserta/2 or assertz/2. Other integers might conflict with the internal consistency of the system. Erase can only be called once on a record or clause. A second call also might conflict with the internal consistency of the system.\footnote{BUG: The system should have a special type for pointers, thus avoiding the Prolog user having to worry about consistency matters. Currently some simple heuristics are used to determine whether a reference is valid.}
102 CHAPTER 4. BUILT-IN PREDICATES

flag(+Key, -Old, +New)

Key is an atom, integer or term. As with the recorded database, if Key is a term, only the name and arity are used to locate the flag. Unify Old with the old value associated with Key. If the key is used for the first time Old is unified with the integer 0. Then store the value of New, which should be an integer, float, atom or arithmetic expression, under Key. flag/3 is a fast mechanism for storing simple facts in the database. The flag database is shared between threads and updates are atomic, making it suitable for generating unique integer counters.\footnote{The flag/3 predicate is not portable. Non-backtrackable global variables (nb_setval/2) and non-backtrackable assignment (nb_setarg/3) are more widely recognised special-purpose alternatives for non-backtrackable and/or global state.}

4.13.1 Update view

Traditionally, Prolog systems used the immediate update view: new clauses became visible to predicates backtracking over dynamic predicates immediately and retracted clauses became invisible immediately.

Starting with SWI-Prolog 3.3.0 we adhere the logical update view, where backtrackable predicates that enter the definition of a predicate will not see any changes (either caused by \texttt{assert/1} or \texttt{retract/1}) to the predicate. This view is the ISO standard, the most commonly used and the most ‘safe’.\footnote{For example, using the immediate update view, no call to a dynamic predicate is deterministic.} Logical updates are realised by keeping reference-counts on predicates and generation information on clauses. Each change to the database causes an increment of the generation of the database. Each goal is tagged with the generation in which it was started. Each clause is flagged with the generation it was created as well as the generation it was erased. Only clauses with ‘created’ … ‘erased’ interval that encloses the generation of the current goal are considered visible.

4.13.2 Indexing databases

By default, SWI-Prolog, as most other implementations, indexes predicates on their first argument. SWI-Prolog allows indexing on other and multiple arguments using the declaration \texttt{index/1}. Dedicated index schemas can be build using \texttt{term_hash/2} or \texttt{term_hash/4}.

term_hash(+Term, -HashKey) \[det\]

If Term is a ground term (see \texttt{ground/1}), HashKey is unified with a positive integer value that may be used as a hash-key to the value. If Term is not ground, the predicate leaves HashKey an unbound variable. Hash keys are in the range 0 \ldots 16, 777, 215, the maximal integer that can be stored efficiently on both 32 and 64 bit platforms.

This predicate may be used to build hash-tables as well as to exploit argument-indexing to find complex terms more quickly.

The hash-key does not rely on temporary information like addresses of atoms and may be assumed constant over different invocations and versions of SWI-Prolog.\footnote{Last change: version 5.6.53} The \texttt{term_hash/2} predicate is cycle-safe. Hashes for numbers differ between bit and little endian machines.

term_hash(+Term, +Depth, +Range, -HashKey) \[det\]

As \texttt{term_hash/2}, but only considers Term to the specified Depth. The toplevel term has depth 1, its arguments have depth 2, etc. I.e. Depth = 0 hashes nothing; Depth = 1 hashes...
atomic values or the functor and arity of a compound term, not its arguments; $Depth = 2$ also indexes the immediate arguments, etc. Using $Depth = -1$ makes term_hash/4 behave as term_hash/2, hashing ground terms to the full depth.

$HashKey$ is in the range $[0 \ldots Range - 1]$. $Range$ must be in the range $[1 \ldots 2147483647]$

### 4.14 Declaring predicates properties

This section describes directives which manipulate attributes of predicate definitions. The functors dynamic/1, multifile/1 and discontiguous/1 are operators of priority 1150 (see op/3), which implies the list of predicates they involve can just be a comma separated list:

```prolog
:- dynamic
    foo/0,
    baz/2.
```

On SWI-Prolog all these directives are just predicates. This implies they can also be called by a program. Do not rely on this feature if you want to maintain portability to other Prolog implementations.

**dynamic** $+PredicateIndicator, \ldots$

Informs the interpreter that the definition of the predicate(s) may change during execution (using assert/1 and/or retract/1). In the multi-threaded version, the clauses of dynamic predicates are shared between the threads. The directive thread_local/1 provides an alternative where each threads has its own clause-list for the predicate. Dynamic predicates can be turned into static ones using compile_predicates/1.

**compile_predicates((ListOfNameArity)**

Compile a list of specified dynamic predicates (see dynamic/1 and assert/1) into normal static predicates. This call tells the Prolog environment the definition will not change anymore and further calls to assert/1 or retract/1 on the named predicates raise a permission error. This predicate is designed to deal with parts of the program that is generated at runtime but does not change during the remainder of the program execution.\(^\text{19}\)

**multifile** $+PredicateIndicator, \ldots$

Informs the system that the specified predicate(s) may be defined over more than one file. This stops consult/1 from redefining a predicate when a new definition is found.

**discontiguous** $+PredicateIndicator, \ldots$

Informs the system that the clauses of the specified predicate(s) might not be together in the source file. See also style_check/1.

**index**(+$Head$)

Index the clauses of the predicate with the same name and arity as $Head$ on the specified arguments. $Head$ is a term of which all arguments are either ‘1’ (denoting ‘index this argument’) or ‘0’ (denoting ‘do not index this argument’). Indexing has no implications for the semantics of a predicate, only on its performance. If indexing is enabled on a predicate a

\(^{19}\)The specification of this predicate is from Richard O’Keefe. The implementation is allowed to optimise the predicate. This is not yet implemented. In multi-threaded Prolog however, static code runs faster as it does not require synchronisation. This is particularly true on SMP hardware.
special purpose algorithm is used to select candidate clauses based on the actual arguments of the goal. This algorithm checks whether indexed arguments might unify in the clause head. Only atoms, integers and compound terms are considered. Compound terms are indexed on the combination of their name and arity. Indexing is very useful for predicates with many clauses representing facts.

Due to the representation technique used at most 4 arguments can be indexed. All indexed arguments should be in the first 32 arguments of the predicate. If more than 4 arguments are specified for indexing only the first 4 will be accepted. Arguments above 32 are ignored for indexing.

Indexing as specified by this predicate uses a quick but linear scan. Without explicit specification the system uses an algorithm depending on the structure of the first argument and number of clauses. In particular, for predicates that can be indexed on the first argument and have many clauses, the system will use an automatically resizing hash-table to provide access time independent from the number of clauses. If—for example—one wants to represents sub-types using a fact list ‘sub_type(Sub, Super)’ that should be used both to determine sub- and super types one should declare sub_type/2 as follows:

```prolog
:- index(sub_type(1, 1)).

sub_type(horse, animal).
...
...
```

Note that this type of indexing makes selecting clauses much faster but remains linear with respect to the number of clauses, while hashing as described with `hash/1` provides constant access time. See also `hash/1` and `term_hash/2`.

**hash(+Head)**

Index the given predicate by hashing on the first argument. This is done by default on any predicate with more than 5 clauses having a first argument that can be indexed and at most two that can not be indexed. On dynamic predicates the hash-table is resized as the number of clauses grows, providing roughly constant-time access regardless of the number of clauses predicates that can be indexed on the first argument. See also `index/1`, `term_hash/2` and `predicate_property/2`.

### 4.15 Examining the program

**current_atom(-Atom)**

Successively unifies `Atom` with all atoms known to the system. Note that `current_atom/1` always succeeds if `Atom` is instantiated to an atom.

**current_blob(?Blob, ?Type)**

Examine the type or enumerate blobs of the given `Type`. Typed blobs are supported through the foreign language interface for storing arbitrary BLOBS (Binary Large Object) or handles to external entities. See section 9.6.6 for details.

---

20SWI-Prolog indexing is no longer state-of-the-art. Better schemas for multi-argument as well as indexing inside compound terms are known. We hope to integrate this in future versions.

---

SWI-Prolog 5.6 Reference Manual
4.15. EXAMINING THE PROGRAM 105

**current_functor**(?Name, ?Arity)
Successively unifies Name with the name and Arity with the arity of functors known to the system.

**current_flag**(-FlagKey)
Successively unifies FlagKey with all keys used for flags (see flag/3).

**current_key**(-Key)
Successively unifies Key with all keys used for records (see recorda/3, etc.).

**current_predicate**(?Name, ?Head)
Successively unifies Name with the name of predicates currently defined and Head with the most general term built from Name and the arity of the predicate. This predicate succeeds for all predicates defined in the specified module, imported to it, or in one of the modules from which the predicate will be imported if it is called.

**current_predicate**(::PredicateIndicator) [ISO]
ISO compliant implementation of current_predicate/2. Unlike current_predicate/2, the current implementation of current_predicate/1 does not consider predicates that can be autoloaded ‘current’.

**predicate_property**(::Head, ?Property)
True if Head refers to a predicate that has property Property. Can be used to test whether a predicate has a certain property, obtain all properties known for Head, find all predicates having property or even obtaining all information available about the current program. Property is one of:

- **built_in**
  Is true if the predicate is locked as a built-in predicate. This implies it cannot be redefined in its definition module and it can normally not be seen in the tracer.

- **dynamic**
  Is true if assert/1 and retract/1 may be used to modify the predicate. This property is set using dynamic/1.

- **exported**
  Is true if the predicate is in the public list of the context module.

- **imported_from**(Module)
  Is true if the predicate is imported into the context module from module Module.

- **file**(FileName)
  Unify FileName with the name of the source file in which the predicate is defined. See also source_file/2.

- **foreign**
  Is true if the predicate is defined in the C language.

- **indexed**(Head)
  Predicate is indexed (see index/1) according to Head. Head is a term whose name and arity are identical to the predicate. The arguments are unified with ‘1’ for indexed arguments, ‘0’ otherwise.
interpolated
Is true if the predicate is defined in Prolog. We return true on this because, although the
code is actually compiled, it is completely transparent, just like interpreted code.

iso
Is true if the predicate is covered by the ISO standard (ISO/IEC 13211-1).

line_count($LineNumber$)
Unify $LineNumber$ with the line number of the first clause of the predicate. Fails if the
predicate is not associated with a file. See also source_file/2.

multifile
Is true there may be multiple (or no) file providing clauses for the predicate. This property
is set using multifile/1.

nodebug
Details of the predicate are not shown by the debugger. This is the default for built-
in predicates. User predicates can be compiled this way using the Prolog flag
generate_debug_info.

notrace
Do not show ports of this predicate in the debugger.

number_of_clauses($ClauseCount$)
Unify $ClauseCount$ to the number of clauses associated with the predicate. Fails for
foreign predicates.

thread_local
If true (only possible on the multi-threaded version) each thread has its own clauses for
the predicate. This property is set using thread_local/1.

transparent
Is true if the predicate is declared transparent using the module_transparent/1
declaration.

undefined
Is true if a procedure definition block for the predicate exists, but there are no clauses for
it and it is not declared dynamic or multifile. This is true if the predicate occurs in the
body of a loaded predicate, an attempt to call it has been made via one of the meta-call
predicates or the predicate had a definition in the past. See the library package check
for example usage.

volatile
If true, the clauses are not saved into a saved-state by qsave_program/[1,2]. This
property is set using volatile/1.

dwim_predicate(+$Term$, -$Dwim$)
‘Do What I Mean’ (‘dwim’) support predicate. $Term$ is a term, which name and arity are
used as a predicate specification. $Dwim$ is instantiated with the most general term built from
Name and the arity of a defined predicate that matches the predicate specified by $Term$ in
the ‘Do What I Mean’ sense. See dwim_match/2 for ‘Do What I Mean’ string matching.
Internal system predicates are not generated, unless style_check(+dollar) is active.
Backtracking provides all alternative matches.
4.16. INPUT AND OUTPUT

clause(:Head, ?Body)

True if Head can be unified with a clause head and Body with the corresponding clause body. Gives alternative clauses on backtracking. For facts Body is unified with the atom true.

clause(:Head, ?Body, ?Reference)

Equivalent to clause/2, but unifies Reference with a unique reference to the clause (see also assert/2, erase/1). If Reference is instantiated to a reference the clause’s head and body will be unified with Head and Body.
	nth_clause(?Pred, ?Index, ?Reference)

Provides access to the clauses of a predicate using their index number. Counting starts at 1. If Reference is specified it unifies Pred with the most general term with the same name/arity as the predicate and Index with the index-number of the clause. Otherwise the name and arity of Pred are used to determine the predicate. If Index is provided Reference will be unified with the clause reference. If Index is unbound, backtracking will yield both the indices and the references of all clauses of the predicate. The following example finds the 2nd clause of member/2:

?- nth_clause(member(_,_), 2, Ref), clause(Head, Body, Ref).

Ref = 160088
Head = system : member(G575, [G578|G579])
Body = member(G575, G579)

clause_property(+ClauseRef, -Property)

Queries properties of a clause. ClauseRef is a reference to a clause as produced by clause/3, nth_clause/3 or prolog_frame_attribute/3. Property is one of the following:

file(FileName)

Unify FileName with the name of the source file in which the clause is defined. Fails if the clause is not associated to a file.

line_count(LineNumber)

Unify LineNumber with the line number of the clause. Fails if the clause is not associated to a file.

fact

True if the clause has no body.

erased

True if the clause has been erased, but not yet reclaimed because it is referenced.

4.16 Input and output

SWI-Prolog provides two different packages for input and output. The native I/O system is based on the ISO standard predicates open/3, close/1 and friends.\(^\text{21}\) Being more widely portable and equipped with a clearer and more robust specification, new code is encouraged to use these predicates for manipulation of I/O streams.

\(^{21}\)Actually based on Quintus Prolog, providing this interface before the ISO standard existed.
Section 4.16.2 describes `tell/1, see/1` and friends, providing I/O in the spirit of the outdated Edinburgh standard. These predicates are layered on top of the ISO predicates. Both packages are fully integrated; the user may switch freely between them.

### 4.16.1 ISO Input and Output Streams

The predicates described in this section provide ISO compliant I/O, where streams are explicitly created using the predicate `open/3`. The resulting stream identifier is then passed as a parameter to the reading and writing predicates to specify the source or destination of the data.

This schema is not vulnerable to filename and stream ambiguities as well as changes to the working directory. New code is advised to use these predicates to manage input and output streams.

**open(+SrcDest, +Mode, -Stream, +Options)**

ISO compliant predicate to open a stream. `SrcDest` is either an atom, specifying a file, or a term `pipe(Command)`, like `see/1` and `tell/1`. `Mode` is one of `read, write, append` or `update`. `Mode append` opens the file for writing, positioning the file-pointer at the end. `Mode update` opens the file for writing, positioning the file-pointer at the beginning of the file without truncating the file. `Stream` is either a variable, in which case it is bound to an integer identifying the stream, or an atom, in which case this atom will be the stream identifier. The `Options` list can contain the following options:

- **type(Type)**
  
  Using `type text` (default), Prolog will write a text-file in an operating-system compatible way. Using `type binary` the bytes will be read or written without any translation. See also the option `encoding`.

- **alias(Atom)**
  
  Gives the stream a name. Below is an example. Be careful with this option as stream-names are global. See also `set_stream/2`.

  ```prolog
  %- open(data, read, Fd, [alias(input)]).
  
  ..., read(input, Term), ...
  ```

- **encoding(Encoding)**
  
  Define the encoding used for reading and writing text to this stream. The default encoding for `type text` is derived from the Prolog flag `encoding`. For `binary` streams the default encoding is `octet`. For details on encoding issues, see section 2.17.1.

- **bom(Bool)**
  
  Check for a BOM (Byte Order Marker) or write one. If omitted, the default is `true` for mode `read` and `false` for mode `write`. See also `stream_property/2` and especially section 2.17.1 for a discussion on this feature.

- **eof_action(Action)**
  
  Defines what happens if the end of the input stream is reached. Action `eof_code` makes

22New code should use the `alias(Alias)` option for compatibility to the ISO standard
get0/1 and friends return -1 and read/1 and friends return the atom end_of_file. Repetitive reading keeps yielding the same result. Action error is like eof.code, but repetitive reading will raise an error. With action reset, Prolog will examine the file again and return more data if the file has grown.

**buffer(Buffering)**

Defines output buffering. The atom full (default) defines full buffering, line buffering by line, and false implies the stream is fully unbuffered. Smaller buffering is useful if another process or the user is waiting for the output as it is being produced. See also flush_output/[0,1]. This option is not an ISO option.

**close_on_abort(Bool)**

If true (default), the stream is closed on an abort (see abort/0). If false, the stream is not closed. If it is an output stream, it will be flushed however. Useful for logfiles and if the stream is associated to a process (using the pipe/1 construct).

**lock(LockingMode)**

Try to obtain a lock on the open file. Default is none, which does not lock the file. The value read or shared means other processes may read the file, but not write it. The value write or exclusive means no other process may read or write the file.

Locks are acquired through the POSIX function fcntl() using the command F_SETLK, which makes a blocked call wait for the lock to be released. Please note that fcntl() locks are advisory and therefore only other applications using the same advisory locks honour your lock. As there are many issues around locking in Unix, especially related to NFS (network file system), please study the fcntl() manual page before trusting your locks!

The lock option is a SWI-Prolog extension.

The option reposition is not supported in SWI-Prolog. All streams connected to a file may be repositioned.

**open(+SrcDest, +Mode, ?Stream)**  
Equivalent to open/4 with an empty option-list.

**open_null_stream(?Stream)**

Open an output stream that produces no output. All counting functions are enabled on such a stream. It can be used to discard output (like Unix /dev/null) or exploit the counting properties. The initial encoding of Stream is utf8, enabling arbitrary Unicode output. The encoding can be changed to determine byte-counts of the output in a particular encoding or validate output is possible in a particular encoding. For example, the code below determines the number of characters emitted when writing Term.

```prolog
write_length(Term, Len) :-
  open_null_stream(Out),
  write(Out, Term),
  character_count(Out, Len0),
  close(Out),
  Len = Len0.
```
close(+Stream)  \hspace{1cm} [ISO]
Close the specified stream. If Stream is not open an error message is displayed. If the closed stream is the current input or output stream the terminal is made the current input or output.

close(+Stream, +Options)  \hspace{1cm} [ISO]
Provides close(Stream, [force(true)]) as the only option. Called this way, any resource error (such as write-errors while flushing the output buffer) are ignored.

stream_property(?Stream, ?StreamProperty)  \hspace{1cm} [ISO]
ISO compatible predicate for querying status of open I/O streams. StreamProperty is one of:

alias(Atom)
If Atom is bound, test of the stream has the specified alias. Otherwise unify Atom with the first alias of the stream.\(^{23}\)

buffer(Buffering)
SWI-Prolog extension to query the buffering mode of this stream. Buffering is one of full, line or false. See also open/4.

buffer_size(Integer)
SWI-Prolog extension to query the size of the I/O buffer associated to a stream in bytes. Fails if the stream is not buffered.

bom(Bool)
If present and true, a BOM (Byte Order Mark) was detected while opening the file for reading or a BOM was written while opening the stream. See section 2.17.1 for details.

encoding(Encoding)
Query the encoding used for text. See section 2.17.1 for an overview of wide character and encoding issues in SWI-Prolog.

end_of_stream(E)
If Stream is an input stream, unify E with one of the atoms not, at or past. See also at_end_of_stream/[0,1].

eof_action(A)
Unify A with one of eof_code, reset or error. See open/4 for details.

file_name(Atom)
If Stream is associated to a file, unify Atom to the name of this file.

file_no(Integer)
If the stream is associated with a POSIX file-descriptor, unify Integer with the descriptor number. SWI-Prolog extension used primarily for integration with foreign code. See also Sfileno() from SWI-Stream.h.

input
True if Stream has mode read.

mode(IOMode)
Unify IOMode to the mode given to open/4 for opening the stream. Values are: read, write, append and the SWI-Prolog extension update.

\(^{23}\)BUG: Backtracking does not give other aliases.
4.16. INPUT AND OUTPUT

**newline(NewlineMode)**
One of posix or dos. If dos, text-streams will emit \r\n for \n and discard \r from input streams. Default depends on the operating system.

**output**
True if Stream has mode write, append or update.

**position(Term)**
Unify Term with the current stream-position. A stream-position is an opaque term whose fields can be extracted using stream_position_data/3. See also set_stream_position/2.

**reposition(Bool)**
Unify Bool with true if the position of the stream can be set (see seek/4). It is assumed the position can be set if the stream has a seek-function and is not based on a POSIX file-descriptor that is not associated to a regular file.

**representation_errors(Mode)**
Determines behaviour of character output if the stream cannot represent a character. For example, an ISO Latin-1 stream cannot represent cyrillic characters. The behaviour is one of error (throw and I/O error exception), prolog (write \...\ escape code or xml (write \&\#...; XML character entity). The initial mode is prolog for the user streams and error for all other streams. See also section 2.17.1 and set_stream/2.

**timeout(-Time)**
Time is the timeout currently associated with the stream. See set_stream/2 with the same option. If no timeout is specified, Time is unified to the atom infinite.

**type(T)**
Unify Bool with text or binary.

**tty(Bool)**
This property is reported with Bool equals true if the stream is associated with a terminal. See also set_stream/2.

**current_stream(?Object, ?Mode, ?Stream)**
The predicate current_stream/3 is used to access the status of a stream as well as to generate all open streams. Object is the name of the file opened if the stream refers to an open file, an integer file-descriptor if the stream encapsulates an operating-system stream or the atom [] if the stream refers to some other object. Mode is one of read or write.

**is_stream(+Term)**
True if Term is a stream name or valid stream handle. This predicate realises a safe test for the existence of a stream alias or handle.

**set_stream_position(+Stream, +Pos)**
Set the current position of Stream to Pos. Pos is a term as returned by stream_property/2 using the position(Pos) property. See also seek/4.

**stream_position_data(?Field, +Position, -Data)**
Extracts information from the opaque stream position term as returned by stream_property/2 requesting the position(Position) property. Field is one
of line_count, line_position, char_count or byte_count. See also line_count/2, line_position/2, character_count/2 and byte_count/2.\(^\text{24}\)

**seek(+Stream, +Offset, +Method, -NewLocation)**

Reposition the current point of the given `Stream`. `Method` is one of `bof`, `current` or `eof`, indicating positioning relative to the start, current point or end of the underlying object. `NewLocation` is unified with the new offset, relative to the start of the stream.

Positions are counted in ‘units’. A unit is 1 byte, except for text-files using 2-byte Unicode encoding (2 bytes) or wchar encoding (`sizeof(wchar_t)`). The latter guarantees comfortable interaction with wide-character text-objects. Otherwise, the use of `seek/4` on non-binary files (see `open/4`) is of limited use, especially when using multi-byte text-encodings (e.g. UTF-8) or multi-byte newline files (e.g. DOS/Windows). On text-files, SWI-Prolog offers reliable backup to an old position using `stream_property/2` and `set_stream_position/2`. Skipping \(N\) character codes is achieved calling `get_code/2 \(N\)` times or using `copy_stream_data/3`, directing the output to a null-stream (see `open_null_stream/1`). If the seek modifies the current location, the line number and character position in the line are set to 0.

If the stream cannot be repositioned, a `permission_error` is raised. If applying the offset would result in a file-position less then zero, a `domain_error` is raised. Behaviour when seeking to positions beyond the size of the underlying object depend on the object and possibly the operating system. The predicate `seek/4` is compatible to Quintus Prolog, though the error conditions and signalling is ISO compliant. See also `stream_property/2` and `set_stream_position/2`.

**set_stream(+Stream, +Attribute)**

Modify an attribute of an existing stream. `Attribute` specifies the stream property to set. See also `stream_property/2` and `open/4`.

**alias(AliasName)**

Set the alias of an already created stream. If `AliasName` is the name of one of the standard streams is used, this stream is rebound. Thus, `set_stream(S, current_input)` is the same as `set_input/1` and by setting the alias of a stream to `user_input`, etc. all user terminal input is read from this stream. See also `interactor/0`.

**buffer(Buffering)**

Set the buffering mode of an already created stream. Buffering is one of `full`, `line` or `false`.

**buffer_size(+Size)**

Set the size of the I/O buffer of the underlying stream to `Size` bytes.

**close_on_abort(Bool)**

Determine whether or not the stream is closed by `abort/0`. By default streams are closed.

**encoding(Atom)**

Defines the mapping between bytes and character codes used for the stream. See section 2.17.1 for supported encodings.

\(^{24}\)Introduced in version 5.6.4 after extending the position term with a byte-count. Compatible with SICStus Prolog.
4.16. INPUT AND OUTPUT

**eof_action** (*Action*)

Set end-of-file handling to one of `eof_code`, `reset` or `error`.

**newline** (*NewlineMode*)

Set input or output translation for newlines. See corresponding `stream_property/2` for details. In addition to the detected modes, an input stream can be set in mode `detect`. It will be set to `dos` if a `\r` character was removed.

**timeout** (*Seconds*)

This option can be used to make streams generate an exception if it takes longer than `Seconds` before any new data arrives at the stream. The value `infinite` (default) makes the stream block indefinitely. Like `wait_for_input/3`, this call only applies to streams that support the `select()` system call. For further information about timeout handling, see `wait_for_input/3`. The exception is of the form

```prolog
error(timeout_error(read, Stream), _)
```

**record_position** (*Bool*)

Do/do not record the line-count and line-position (see `line_count/2` and `line_position/2`).

**representation_errors** (*Mode*)

Change the behaviour when writing characters to the stream that cannot be represented by the encoding. See also `stream_property/2` and section 2.17.1.

**file_name** (*FileName*)

Set the file name associated to this stream. This call can be used to set the file for error-locations if `Stream` corresponds to `FileName` and is not obtained by opening the file directly but, for example, through a network service.

**tty** (*Bool*)

Modify whether Prolog thinks there is a terminal (i.e. human interaction) connected to this stream. On Unix systems the initial value comes from `isatty()`. On Windows, the initial user streams are supposed to be associated to a terminal. See also `stream_property/2`. The `clib` package provides the library `prolog_server` creating a TCP/IP server for creating an interactive session to Prolog.

**set_prolog_IO** (+In, +Out, +Error)

Prepare the given streams for interactive behaviour normally associated to the terminal. `In` becomes the `user_input` and `current_input` of the calling thread. `Out` becomes `user_output` and `current_output`. If `Error` equals `Out` an unbuffered stream is associated to the same destination and linked to `user_error`. Otherwise `Error` is used for `user_error`. Output buffering for `Out` is set to `line` and buffering on `Error` is disabled. See also `prolog/0` and `set_stream/2`. The `clib` package provides the library `prolog_server` creating a TCP/IP server for creating an interactive session to Prolog.

4.16.2 Edinburgh-style I/O

The package for implicit input and output destination is (almost) compatible to Edinburgh DEC-10 and C-Prolog. The reading and writing predicates refer to resp. the `current` input- and output stream. Initially these streams are connected to the terminal. The current output stream is changed using `tell/1` or `append/1`. The current input stream is changed using `see/1`. The streams current value can be obtained using `telling/1` for output- and `seeing/1` for input streams.
Source and destination are either a file, user, or a term ‘pipe(Command)’. The reserved stream name user refers to the terminal. In the predicate descriptions below we will call the source/destination argument ‘SrcDest’. Below are some examples of source/destination specifications.

?- see(data). % Start reading from file ‘data’.
?- tell(user). % Start writing to the terminal.
?- tell(pipe(lpr)). % Start writing to the printer.

Another example of using the pipe/1 construct is shown below. Note that the pipe/1 construct is not part of Prolog’s standard I/O repertoire.

getwd(Wd) :-
    seeing(Old), see(pipe(pwd)),
    collect_wd(String),
    seen, see(Old),
    atom_codes(Wd, String).

collect_wd([C|R]) :-
    get0(C), C \== -1, !,
    collect_wd(R).
collect_wd([]).

Compatibility notes

Unlike Edinburgh Prolog systems, telling/1 and seeing/1 do not return the filename of the current input/output, but the stream-identifier, to ensure the design pattern below works under all circumstances.

\[\ldots,\]
\[\text{telling}(	ext{Old}), \text{tell}(x),\]
\[\ldots,\]
\[\text{told}, \text{tell}(	ext{Old}),\]
\[\ldots,\]

The predicates tell/1 and see/1 first check for user, the pipe(command) and a stream-handle. Otherwise, if the argument is an atom it is first compared to open streams associated to a file with exactly the same name. If such a stream, created using tell/1 or see/1 exists, output (input) is switch to the open stream. Otherwise a file with the specified name is opened.

The behaviour is compatible to Edinburgh Prolog. This is not without problems. Changing directory, non-file streams, multiple names referring to the same file easily lead to unexpected behaviour.

New code, especially when managing multiple I/O channels should consider using the ISO I/O predicates defined in section 4.16.1.

\[25\text{The ISO I/O layer uses user_input, user_output and user_error.}\]
\[26\text{As of version 5.3.15, the pipe construct is supported in the MS-Windows version, both for plcon.exe and plwin.exe. The implementation uses code from the LUA programming language (http://www.lua.org).}\]
\[27\text{Filenames can be ambiguous and SWI-Prolog streams can refer to much more than just files.}\]
4.16. INPUT AND OUTPUT

see(+SrcDest)
Open SrcDest for reading and make it the current input (see set_input/1). If SrcDest is a stream-handle, just makes this stream the current input. See the introduction of section 4.16.2 for details.

tell(+SrcDest)
Open SrcDest for writing and make it the current output (see set_output/1). If SrcDest is a stream-handle, just makes this stream the current output. See the introduction of section 4.16.2 for details.

append(+File)
Similar to tell/1, but positions the file pointer at the end of File rather than truncating an existing file. The pipe construct is not accepted by this predicate.

seeing(?SrcDest)
Same as current_input/1, except that user is returned if the current input is the stream user_input to improve compatibility with traditional Edinburgh I/O. See the introduction of section 4.16.2 for details.

telling(?SrcDest)
Same as current_output/1, except that user is returned if the current output is the stream user_output to improve compatibility with traditional Edinburgh I/O. See the introduction of section 4.16.2 for details.

seen
Close the current input stream. The new input stream becomes user_input.

told
Close the current output stream. The new output stream becomes user_output.

4.16.3 Switching Between Edinburgh and ISO I/O

The predicates below can be used for switching between the implicit- and the explicit stream based I/O predicates.

set_input(+Stream) [ISO]
Set the current input stream to become Stream. Thus, open(file, read, Stream), set_input(Stream) is equivalent to see(file).

set_output(+Stream) [ISO]
Set the current output stream to become Stream. See also with_output_to/2.

current_input(-Stream) [ISO]
Get the current input stream. Useful to get access to the status predicates associated with streams.

current_output(-Stream) [ISO]
Get the current output stream.
4.16.4 Write onto atoms, code-lists, etc.

with_output_to(+Output, :Goal)
Run Goal as once/1, while characters written to the current output is sent to Output. The predicate is SWI-Prolog specific, inspired by various posts to the mailinglist. It provides a flexible replacement for predicates such as sformat/3, swritef/3, term_to_atom/2, atom_number/2 converting numbers to atoms, etc. The predicate format/3 accepts the same terms as output argument.

Applications should generally avoid creating atoms by breaking and concatenating other atoms as the creation of large numbers of intermediate atoms generally leads to poor performance, even more so in multi-threaded applications. This predicate supports creating difference-lists from character data efficiently. The example below defines the DCG rule term//1 to insert a term in the output:

\[
\text{term}(\text{Term}, \text{In}, \text{Tail}) :- \\
\quad \text{with_output_to}(\text{codes}(\text{In}, \text{Tail}), \text{write}(\text{Term})).
\]

?- phrase(term(hello), X).

A Stream handle or alias
Temporary switch current output to the given stream. Redirection using with_output_to/2 guarantees the original output is restored, also if Goal fails or raises an exception. See also call_cleanup/2.

atom(-Atom)
Create an atom from the emitted characters. Please note the remark above.

string(-String)
Create a string-object as defined in section 4.23.

codes(-Codes)
Create a list of character codes from the emitted characters, similar to atom_codes/2.

codes(-Codes, -Tail)
Create a list of character codes as a difference-list.

chars(-Chars)
Create a list of one-character-atoms codes from the emitted characters, similar to atom_chars/2.

chars(-Chars, -Tail)
Create a list of one-character-atoms as a difference-list.

4.17 Status of streams

wait_for_input(+ListOfStreams, -ReadyList, +TimeOut)
Wait for input on one of the streams in ListOfStreams and return a list of streams on which input is available in ReadyList. wait_for_input/3 waits for at most TimeOut seconds.
**4.17. STATUS OF STREAMS**

*Timeout* may be specified as a floating point number to specify fractions of a second. If *Timeout* equals *infinite*, `wait_for_input/3` waits indefinitely.\(^{28}\)

This predicate can be used to implement timeout while reading and to handle input from multiple sources. The following example will wait for input from the user and an explicitly opened second terminal. On return, *Inputs* may hold `user` or `P4` or both.

```prolog
?- open('/dev/ttyp4', read, P4),
   wait_for_input([user, P4], Inputs, 0).
```

This predicate relies on the `select()` call on most operating systems. On Unix this call is implemented for any stream referring to a file-handle, which implies all OS-based streams: sockets, terminals, pipes, etc. On non-Unix systems `select()` is generally only implemented for socket-based streams. See also `socket` from the `clib` package.

Note that `wait_for_input/3` returns streams that have data waiting. This does not mean you can, for example, call `read/2` on the stream without blocking as the stream might hold an incomplete term. The predicate `set_stream/2` using the option `timeout`(`Seconds`) can be used to make the stream generate an exception if no new data arrives for within the timeout.

Suppose two processes communicate by exchanging Prolog terms. The following code makes the server immune for clients that write an incomplete term:

```prolog
..., tcp_accept(Server, Socket, _Peer),
tcp_open(Socket, In, Out),
set_stream(In, timeout(10)),
catch(read(In, Term), _, (close(Out), close(In), fail)),
..., byte_count(+Stream, -Count)

Byte-position in *Stream*. For binary streams this is the same as `character_count/2`. For text files the number may be different due to multi-byte encodings or additional record separators (such as Control-M in Windows).

character_count(+Stream, -Count)

Unify *Count* with the current character index. For input streams this is the number of characters read since the open, for output streams this is the number of characters written. Counting starts at 0.

line_count(+Stream, -Count)

Unify *Count* with the number of lines read or written. Counting starts at 1.

line_position(+Stream, -Count)

Unify *Count* with the position on the current line. Note that this assumes the position is 0 after the open. Tabs are assumed to be defined on each 8-th character and backspaces are assumed to reduce the count by one, provided it is positive.

\(^{28}\) For compatibility reasons, a *Timeout* value of 0 (integer) also waits indefinitely. To call `select()` without giving up the CPU pass the float 0.0. If compatibility with versions older than 5.1.3 is desired pass the float value 1e-7.
fileerrors(-Old, +New)

Define error behaviour on errors when opening a file for reading or writing. Valid values are the atoms on (default) and off. First Old is unified with the current value. Then the new value is set to New.\(^\text{29}\)

With the introduction of exception-handling, it is advised to use catch/3 to catch possibly file-errors and act accordingly. Note that if fileerrors is off, no exception is generated.

### 4.18 Primitive character I/O

See section 4.2 for an overview of supported character representations.

**nl**  
Write a newline character to the current output stream. On Unix systems nl/0 is equivalent to put(10).

**nl(+Stream)**  
Write a newline to Stream.

**put(+Char)**  
Write Char to the current output stream. Char is either an integer-expression evaluating to a character code or an atom of one character. Deprecated. New code should use put_char/1 or put_code/1.

**put(+Stream, +Char)**  
Write Char to Stream. See put/1 for details.

**put_byte(+Byte)**  
Write a single byte to the output. Byte must be an integer between 0 and 255.

**put_byte(+Stream, +Byte)**  
Write a single byte to a stream. Byte must be an integer between 0 and 255.

**put_char(+Char)**  
Write a character to the current output, obeying the encoding defined for the current output stream. Note that this may raise an exception if the encoding of Stream cannot represent Char.

**put_char(+Stream, +Char)**  
Write a character to Stream, obeying the encoding defined for Stream. Note that this may raise an exception if the encoding of Stream cannot represent Char.

**put_code(+Code)**  
Similar to put_char/1, but using a character code. Code is a non-negative integer. Note that this may raise an exception if the encoding of Stream cannot represent Code.

**put_code(+Stream, +Code)**  
Same as put_code/1 but directing Code to Stream.

\(^{29}\)Note that Edinburgh Prolog defines fileerrors/0 andnofileerrors/0. As this does not allow you to switch back to the old mode I think this definition is better.
4.18. PRIMITIVE CHARACTER I/O

\textbf{tab(+Amount)}

Writes \textit{Amount} spaces on the current output stream. \textit{Amount} should be an expression that evaluates to a positive integer (see section 4.26).

\textbf{tab(+Stream, +Amount)}

Writes \textit{Amount} spaces to \textit{Stream}.

\textbf{flush\_output} \hfill [ISO]

Flush pending output on current output stream. \texttt{flush\_output/0} is automatically generated by \texttt{read/1} and derivatives if the current input stream is \texttt{user} and the cursor is not at the left margin.

\textbf{flush\_output(+Stream)} \hfill [ISO]

Flush output on the specified stream. The stream must be open for writing.

\textbf{ttyflush}

Flush pending output on stream \texttt{user}. See also \texttt{flush\_output/[0,1]}.

\textbf{get\_byte(-Byte)} \hfill [ISO]

Read the current input stream and unify the next byte with \texttt{Byte} (an integer between 0 and 255. \texttt{Byte} is unified with -1 on end of file.

\textbf{get\_byte(+Stream, -Byte)} \hfill [ISO]

Read the next byte from \texttt{Stream}, returning an integer between 0 and 255.

\textbf{get\_code(-Code)} \hfill [ISO]

Read the current input stream and unify \texttt{Code} with the character code of the next character. \texttt{Code} is unified with -1 on end of file. See also \texttt{get\_char/1}.

\textbf{get\_code(+Stream, -Code)} \hfill [ISO]

Read the next character-code from \texttt{Stream}.

\textbf{get\_char(-Char)} \hfill [ISO]

Read the current input stream and unify \texttt{Char} with the next character as a one-character-atom. See also \texttt{atom\_chars/2}. On end-of-file, \texttt{Char} is unified to the atom \texttt{end\_of\_file}.

\textbf{get\_char(+Stream, -Char)} \hfill [ISO]

Unify \texttt{Char} with the next character from \texttt{Stream} as a one-character-atom. See also \texttt{get\_char/2, get\_byte/2} and \texttt{get\_code/2}.

\textbf{get0(-Char)}

Edinburgh version of the ISO \texttt{get\_code/1} predicate. Note that Edinburgh prolog didn’t support wide characters and therefore technically speaking \texttt{get0/1} should have been mapped to \texttt{get\_byte/1}. The intention of \texttt{get0/1} however is to read character codes.

\textbf{get0(+Stream, -Char)}

Edinburgh version of the ISO \texttt{get\_code/2} predicate. See also \texttt{get0/1}.

\textbf{get(-Char)}

Read the current input stream and unify the next non-blank character with \texttt{Char}. \texttt{Char} is unified with -1 on end of file.
get(+Stream, -Char)
    Read the next non-blank character from Stream.

peek_byte(-Byte)                   [ISO]
    Reads the next input byte like get_byte/1, but does not remove it from the input stream.

peek_byte(+Stream, -Byte)          [ISO]
    Reads the next input byte like get_byte/2, but does not remove it from the stream.

peek_code(-Code)                   [ISO]
    Reads the next input code like get_code/1, but does not remove it from the input stream.

peek_code(+Stream, -Code)          [ISO]
    Reads the next input code like get_code/2, but does not remove it from the stream.

peek_char(-Char)                   [ISO]
    Reads the next input character like get_char/1, but does not remove it from the input stream.

peek_char(+Stream, -Char)          [ISO]
    Reads the next input character like get_char/2, but does not remove it from the stream.

skip(+Code)
    Read the input until Char or the end of the file is encountered. A subsequent call to get_code/1 will read the first character after Code.

skip(+Stream, +Code)
    Skip input (as skip/1) on Stream.

get_single_char(-Code)
    Get a single character from input stream ‘user’ (regardless of the current input stream). Unlike get_code/1 this predicate does not wait for a return. The character is not echoed to the user’s terminal. This predicate is meant for keyboard menu selection etc. If SWI-Prolog was started with the -tty option this predicate reads an entire line of input and returns the first non-blank character on this line, or the character code of the newline (10) if the entire line consisted of blank characters.

at_end_of_stream                  [ISO]
    Succeeds after the last character of the current input stream has been read. Also succeeds if there is no valid current input stream.

at_end_of_stream(+Stream)         [ISO]
    Succeeds after the last character of the named stream is read, or Stream is not a valid input stream. The end-of-stream test is only available on buffered input stream (unbuffered input streams are rarely used, see open/4).

copy_stream_data(+StreamIn, +StreamOut, +Len)
    Copy Len codes from stream StreamIn to StreamOut. Note that the copy is done using the semantics of get_code/2 and put_code/2, taking care of possibly recoding that needs take place between two text files. See section 2.17.1.

copy_stream_data(+StreamIn, +StreamOut)
    Copy data all (remaining) data from stream StreamIn to StreamOut.
4.19 Term reading and writing

This section describes the basic term reading and writing predicates. The predicates format/[1,2] and writef/2 provide formatted output. Writing to Prolog datastructures such as atoms or code-lists is supported by with_output_to/2 and format/3.

There are two ways to manipulate the output format. The predicate print/[1,2] may be programmed using portray/1. The format of floating point numbers may be manipulated using the Prolog flag float_format.

Reading is sensitive to the Prolog flag character_escapes, which controls the interpretation of the \ character in quoted atoms and strings.

write_term(+Term, +Options) [ISO]

The predicate write_term/2 is the generic form of all Prolog term-write predicates. Valid options are:

attributes(Atom)
Define how attributed variables (see section 6.1) are written. The default is determined by the Prolog flag write_attributes. Defined values are ignore (ignore the attribute), dots (write the attributes as {...}), write (simply hand the attributes recursively to write_term/2) and portray (hand the attributes to attr_portray_hook/2).

backquoted_string(Bool)
If true, write a string object (see section 4.23) as ‘…’. The default depends on the Prolog flag backquoted_string.
character_escapes(Bool)
If true, and quoted(true) is active, special characters in quoted atoms and strings are emitted as ISO escape-sequences. Default is taken from the reference module (see below).

ignore_ops(Bool)
If true, the generic term-representation (⟨functor⟩(⟨args⟩ ...)) will be used for all terms, Otherwise (default), operators, list-notation and {}/1 will be written using their special syntax.

max_depth(Integer)
If the term is nested deeper than Integer, print the remainder as eclipse (...). A 0 (zero) value (default) imposes no depth limit. This option also delimits the number of printed for a list. Example:

?- write_term(a(s(s(s(s(0)))), [a,b,c,d,e,f]), [max_depth(3)]).
a(s(s(...)), [a, b|...])

Yes

Used by the top-level and debugger to limit screen output. See also the Prolog flags toplevel_print_options and debugger_print_options.

module(Module)
Define the reference module (default user). This defines the default value for the character_escapes option as well as the operator definitions to use. See also op/3.

numbervars(Bool)
If true, terms of the format $\langle N \rangle$, where $\langle N \rangle$ is a positive integer, will be written as a variable name. If $N$ is an atom it is written without quotes. This extension allows for writing variables with user-provided names. The default is false. See also numbervars/3.

portray(Bool)
If true, the hook portray/1 is called before printing a term that is not a variable. If portray/1 succeeds, the term is considered printed. See also print/1. The default is false. This option is an extension to the ISO write_term options.

priority(Integer)
An integer between 0 and 1200 representing the ‘context priority’. Default is 1200. Can be used to write partial terms appearing as the argument to an operator. For example:

format(‘\w = ’, [VarName]),
write_term(Value, [quoted(true), priority(699)])

quoted(Bool)
If true, atoms and functors that needs quotes will be quoted. The default is false.

write_term(+Stream, +Term, +Options)
As write_term/2, but output is sent to Stream rather than the current output.

write_canonical(+Term)
Write Term on the current output stream using standard parenthesised prefix notation (i.e.,
ignoring operator declarations). Atoms that need quotes are quoted. Terms written with this predicate can always be read back, regardless of current operator declarations. Equivalent to \texttt{write_term/2} using the options \texttt{ignore_ops}, \texttt{quoted} and \texttt{numbervars} after \texttt{numbervars/4} using the \texttt{singleton} option.

Note that due to the use of \texttt{numbervars/4}, non-ground terms must be written using a \texttt{single} \texttt{write_canonical/1} call. This used to be the case anyhow, as garbage collection between multiple calls to one of the write predicates can change the \texttt{_G(NNN)} identity of the variables.

\begin{verbatim}
write_canonical(+Stream, +Term) \hfill [ISO]
  Write Term in canonical form on Stream.

write(+Term) \hfill [ISO]
  Write Term to the current output, using brackets and operators where appropriate. The Prolog flag \texttt{float_format} controls floating point output format.

write(+Stream, +Term) \hfill [ISO]
  Write Term to Stream.

writeq(+Term) \hfill [ISO]
  Write Term to the current output, using brackets and operators where appropriate. Atoms that need quotes are quoted. Terms written with this predicate can be read back with \texttt{read/1} provided the currently active operator declarations are identical.

writeq(+Stream, +Term) \hfill [ISO]
  Write Term to Stream, inserting quotes.

print(+Term) \hfill [ISO]
  Prints Term on the current output stream similar to \texttt{write/1}, but for each (sub)term of Term first the dynamic predicate \texttt{portray/1} is called. If this predicate succeeds \texttt{print} assumes the (sub)term has been written. This allows for user defined term writing.

print(+Stream, +Term) \hfill [ISO]
  Print Term to Stream.

portray(+Term) \hfill [ISO]
  A dynamic predicate, which can be defined by the user to change the behaviour of \texttt{print/1} on (sub)terms. For each subterm encountered that is not a variable \texttt{print/1} first calls \texttt{portray/1} using the term as argument. For lists only the list as a whole is given to \texttt{portray/1}. If \texttt{portray} succeeds \texttt{print/1} assumes the term has been written.

read(-Term) \hfill [ISO]
  Read the next Prolog term from the current input stream and unify it with Term. On a syntax error \texttt{read/1} displays an error message, attempts to skip the erroneous term and fails. On reaching end-of-file Term is unified with the atom \texttt{end_of_file}.

read(+Stream, -Term) \hfill [ISO]
  Read Term from Stream.

read_clause(-Term) \hfill [ISO]
  Equivalent to \texttt{read/1}, but warns the user for variables only occurring once in a
\end{verbatim}
term (singleton variables, see section 2.15.1) which do not start with an underscore
if style_check(singleton) is active (default). Used to read Prolog source
files (see consult/1). New code should use read_term/2 with the option
singletons(warning).

read_clause(+Stream, -Term)
Read a clause from Stream. See read_clause/1.

read_term(-Term, +Options)
Read a term from the current input stream and unify the term with Term. The reading is con-
trolled by options from the list of Options. If this list is empty, the behaviour is the same as
for read/1. The options are upward compatible to Quintus Prolog. The argument order is
according to the ISO standard. Syntax-errors are always reported using exception-handling
(see catch/3). Options:

backquoted_string(Bool)
If true, read ’...’ to a string object (see section 4.23). The default depends on the
Prolog flag backquoted_string.

character_escapes(Bool)
Defines how to read \ escape-sequences in quoted atoms. See the Prolog flags
character_escapes, current_prolog_flag/2. (SWI-Prolog).

comments(-Comments)
Unify Comments with a list of Position-Comment, where Position is a stream-position
object (see stream_position_data/3) indicating the start of a comment and
Comment is a string-object containing the text including delimiters of a comment. It
returns all comments from where the read_term/2 call started upto the end of the term
read.

double_quotes(Bool)
Defines how to read ”...” strings. See the Prolog flag double_quotes. (SWI-Prolog).

module(Module)
Specify Module for operators, character_escapes flag and double_quotes flag.
The value of the latter two is overruled if the corresponding read_term/3 option is
provided. If no module is specified, the current ‘source-module’ is used. (SWI-Prolog).

singletons(Vars)
As variable_names, but only reports the variables occurring only once in the Term
read. Variables starting with an underscore (’_’) are not included in this list. (ISO). If Vars
is the constant warning, singleton variables are reported using print_message/2.

syntax_errors(Atom)
If error (default), throw and exception on a syntax error. Other values are fail, which
causes a message to be printed using print_message/2, after which the predicate
fails, quiet which causes the predicate to fail silently and dec10 which causes syntax
errors to be printed, after which read_term/[2,3] continues reading the next term.
Using dec10, read_term/[2,3] never fails. (Quintus, SICStus).

subterm_positions(TermPos)
Describes the detailed layout of the term. The formats for the various types of terms if
given below. All positions are character positions. If the input is related to a normal

[ISO]
stream, these positions are relative to the start of the input, when reading from the terminal, they are relative to the start of the term.

From-To
Used for primitive types (atoms, numbers, variables).

string_position(From, To)
Used to indicate the position of a string enclosed in double quotes (").

brace_term_position(From, To, Arg)
Term of the form \{ \ldots \}, as used in DCG rules. Arg describes the argument.

list_position(From, To, Elms, Tail)
A list. Elms describes the positions of the elements. If the list specifies the tail as | TailTerm, Tail is unified with the term-position of the tail, otherwise with the atom none.

term_position(From, To, FFrom, FTo, SubPos)
Used for a compound term not matching one of the above. FFrom and FTo describe the position of the functor. SubPos is a list, each element of which describes the term-position of the corresponding subterm.

term_position(Pos)
Unifies Pos with the starting position of the term read. Pos if of the same format as use by stream_property/2.

variables(Vars)
Unify Vars with a list of variables in the term. The variables appear in the order they have been read. See also term_variables/2. (ISO).

variable_names(Vars)
Unify Vars with a list of ‘Name = Var’, where Name is an atom describing the variable name and Var is a variable that shares with the corresponding variable in Term. (ISO).

read_term(+Stream, -Term, +Options)
Read term with options from Stream. See read_term/2.

read_history(+Show, +Help, +Special, +Prompt, -Term, -Bindings)
Similar to read_term/2 using the option variable_names, but allows for history substitutions. read_history/6 is used by the top level to read the user’s actions. Show is the command the user should type to show the saved events. Help is the command to get an overview of the capabilities. Special is a list of commands that are not saved in the history. Prompt is the first prompt given. Continuation prompts for more lines are determined by prompt/2. A %w in the prompt is substituted by the event number. See section 2.7 for available substitutions.

SWI-Prolog calls read_history/6 as follows:

read_history(h, ’!h’, [trace], ’%w ?- ’, Goal, Bindings)

prompt(-Old, +New)
Set prompt associated with read/1 and its derivatives. Old is first unified with the current prompt. On success the prompt will be set to New if this is an atom. Otherwise an error message is displayed. A prompt is printed if one of the read predicates is called and the cursor
is at the left margin. It is also printed whenever a newline is given and the term has not been
terminated. Prompts are only printed when the current input stream is user.

**prompt1(+Prompt)**

Sets the prompt for the next line to be read. Continuation lines will be read using the prompt
defined by prompt/2.

### 4.20 Analysing and Constructing Terms

**functor(?Term, ?Functor, ?Arity)**  
True if Term is a term with functor Functor and arity Arity. If Term is a variable it is unified
with a new term holding only variables. functor/3 silently fails on instantiation faults. If Term
is an atom or number, Functor will be unified with Term and arity will be unified with the
integer 0 (zero).

**arg(?Arg, +Term, ?Value)**  
Term should be instantiated to a term, Arg to an integer between 1 and the arity of Term. Value
is unified with the Arg-th argument of Term. Arg may also be unbound. In this case Value
will be unified with the successive arguments of the term. On successful unifica-
tion, Arg is unified with the argument number. Backtracking yields alternative solutions.
The predicate arg/3 fails silently if Arg = 0 or Arg > arity and raises the exception
domain_error(not_less_than_zero, Arg) if Arg < 0.

?Term = .. ?List

List is a list which head is the functor of Term and the remaining arguments are the arguments
of the term. Each of the arguments may be a variable, but not both. This predicate is called
‘Univ’. Examples:

?- foo(hello, X) =.. List.

List = [foo, hello, X]

?- Term =.. [baz, foo(1)]

Term = baz(foo(1))

**numbervars(+Term, +Start, -End)**

Unify the free variables of Term with a term $VAR(N)$, where N is the number of the variable.
Counting starts at Start. End is unified with the number that should be given to the next
variable. Example:

?- numbervars(foo(A, B, A), 0, End).

---

30 In version 1.2 instantiation faults led to error messages. The new version can be used to do type testing without the
need to catch illegal instantiations first.

31 The instantiation pattern (-, +, ?) is an extension to ‘standard’ Prolog. Some systems provide genarg/3 that covers
this pattern.
A = 'VAR'(0)
B = 'VAR'(1)
End = 2

See also the numbervars option to write_term/3 and numbervars/4.

numbervars(+Term, +Start, -End, +Options)
As numbervars/3, but providing the following options:

functor_name(+Atom)
Name of the functor to use instead of $VAR.$

attvar(+Action)
What to do if an attributed variable is encountered. Options are skip, which causes numbervars/3 to ignore the attributed variable, bind which causes it to thread it as a normal variable and assign the next '$VAR'(N) term to it or (default) error which raises the a type_error exception.\(^{32}\)

singleton(+Bool)
If true (default false), numbervars/4 does singleton detection. Singleton variables are unified with '$VAR'('_'), causing them to be printed as _ by write_term/2 using the numbervars option. This option is exploited by portray.clause/2 and write.canonical/2.\(^{33}\)

term_variables(+Term, -List)
Unify List with a list of variables, each sharing with a unique variable of Term.\(^{34}\) The variables in List are ordered in order of appearance traversing Term depth-first and left-to-right. See also term.variables/3. For example:

?- term_variables(a(X, b(Y, X), Z), L).

L = [G367, G366, G371]
X = G367
Y = G366
Z = G371

term_variables(+Term, -List, ?Tail)
Difference list version of term.variables/2. I.e. Tail is the tail of the variable-list List.

copy_term(+In, -Out)\(^{[ISO]}\)
Create a version if In with renamed (fresh) variables and unify it to Out. Attributed variables (see section 6.1) have their attributed copied. The implementation of copy_term/2 can deal with infinite trees (cyclic terms). As pure Prolog cannot distinguish a ground term from another ground term with exactly the same structure, ground sub-terms are shared between In and Out. Sharing ground terms does affect setarg/3. SWI-Prolog provides duplicate_term/2 to create a true copy of a term.

---

\(^{32}\)This behaviour was decided after a long discussion between David Reitter, Richard O’Keefe, Bart Demoen and Tom Schrijvers.

\(^{33}\)BUG: Currently this option is ignored for cyclic terms.

\(^{34}\)This predicate used to be called free.variables/2. The name term.variables/2 is more widely used. The old predicate is still available from the library backcomp.
4.20.1 Non-logical operations on terms

Prolog is not capable to modify instantiated parts of a term. Lacking that capability makes that language much safer, but unfortunately there are problems that suffer severely in terms of time and/or memory usage. Always try hard to avoid the use of these primitives, but they can be a good alternative to using dynamic predicates. See also section 6.3, discussing the use of global variables.

setarg(+Arg, +Term, +Value)
Extra-logical predicate. Assigns the Arg-th argument of the compound term Term with the given Value. The assignment is undone if backtracking brings the state back into a position before the setarg/3 call. See also nb_setarg/3.

This predicate may be used for destructive assignment to terms, using them as an extra-logical storage bin. Always try hard to avoid the use of setarg/3 as it is not supported by many Prolog systems and one has to be very careful about unexpected copying as well as unexpected not copying of terms.

nb_setarg(+Arg, +Term, +Value)
Assigns the Arg-th argument of the compound term Term with the given Value as setarg/3, but on backtracking the assignment is not reversed. If Term is not atomic, it is duplicated using duplicate_term/2. This predicate uses the same technique as nb_setval/2. We therefore refer to the description of nb_setval/2 for details on non-backtrackable assignment of terms. This predicate is compatible to GNU-Prolog setarg(A,T,V,false), removing the type-restriction on Value. See also nb_linkarg/3. Below is an example for counting the number of solutions of a goal. Note that this implementation is thread-safe, reentrant and capable of handling exceptions. Realising these features with a traditional implementation based on assert/retract or flag/3 is much more complicated.

succeeds_n_times(Goal, Times) :-
  Counter = counter(0),
  ( Goal,
    arg(1, Counter, N0),
    N is N0 + 1,
    nb_setarg(1, Counter, N),
    fail
  ; arg(1, Counter, Times)
  ).

nb_linkarg(+Arg, +Term, +Value)
As nb_setarg/3, but like nb_linkval/2 it does not duplicate Value. Use with extreme care and consult the documentation of nb_linkval/2 before use.

duplicate_term(+In, -Out)
Version of copy_term/2 that also copies ground terms and therefore ensures destructive modification using setarg/3 does not affect the copy. See also nb_setval/2, nb_linkval/2, nb_setarg/3 and nb_linkarg/3.
4.21. ANALYSING AND CONSTRUCTING ATOMS

same_term(@T1, @T2)  
True if T1 and T2 are the equivalent and will remain the equivalent, even if setarg/3 is used on either of them. This means T1 and T2 are the same variable, equivalent atomic data or a compound term allocated at the same address.

4.21 Analysing and Constructing Atoms

These predicates convert between Prolog constants and lists of character codes. The predicates atom_codes/2, number_codes/2 and name/2 behave the same when converting from a constant to a list of character codes. When converting the other way around, atom_codes/2 will generate an atom, number_codes/2 will generate a number or exception and name/2 will return a number if possible and an atom otherwise.

The ISO standard defines atom_chars/2 to describe the ‘broken-up’ atom as a list of one-character atoms instead of a list of codes. Up-to version 3.2.x, SWI-Prolog’s atom_chars/2 behaved, compatible to Quintus and SICStus Prolog, like atom_codes. As of 3.3.x SWI-Prolog atom_codes/2 and atom_chars/2 are compliant to the ISO standard.

To ease the pain of all variations in the Prolog community, all SWI-Prolog predicates behave as flexible as possible. This implies the ‘list-side’ accepts either a code-list or a char-list and the ‘atom-side’ accept all atomic types (atom, number and string).

atom_codes(?Atom, ?String)  
Convert between an atom and a list of character codes. If Atom is instantiated, it will be translated into a list of character codes and the result is unified with String. If Atom is unbound and String is a list of character codes, it will Atom be unified with an atom constructed from this list.

atom_chars(?Atom, ?CharList)  
As atom_codes/2, but CharList is a list of one-character atoms rather than a list of character codes\(^{35}\).

?- atom_chars(hello, X).

X = [h, e, l, l, o]

char_code(?Atom, ?Code)  
Convert between character and character code for a single character.\(^{36}\)

number_chars(?Number, ?CharList)  
Similar to atom_chars/2, but converts between a number and its representation as a list of one-character atoms. Fails with a syntax_error if Number is unbound and CharList does not describe a number.

\(^{35}\)Up-to version 3.2.x, atom_chars/2 behaved as the current atom_codes/2. The current definition is compliant with the ISO standard

\(^{36}\)This is also called atom_char/2 in older versions of SWI-Prolog as well as some other Prolog implementations. The atom_char/2 predicate is available from the library backcomp.pl
number_codes(?Number, ?CodeList)

As number_chars/2, but converts to a list of character codes rather than one-character atoms. In the mode -, +, both predicates behave identically to improve handling of non-ISO source.

atom_number(?Atom, ?Number)

Realises the popular combination of atom_codes/2 and number_codes/2 to convert between atom and number (integer or float) in one predicate, avoiding the intermediate list. Calling in mode +,- to convert numbers represented as atoms is often good style. Converting numbers to atoms, which in turn are assembled into larger units before communication them to the outside world is bad style. Consider using streams or with_output_to/2 to reduce the number of expensive intermediate atoms.

name(?AtomOrInt, ?String)

String is a list of character codes representing the same text as Atom. Each of the arguments may be a variable, but not both. When String is bound to an character code list describing an integer and Atom is a variable Atom will be unified with the integer value described by String (e.g. 'name(N, "300"), 400 is N + 100 succeeds).

term_to_atom(?Term, ?Atom)

True if Atom describes a term that unifies with Term. When Atom is instantiated Atom is converted and then unified with Term. If Atom has no valid syntax, a syntax_error exception is raised. Otherwise Term is “written” on Atom using write/1.

atom_to_term(+Atom, -Term, -Bindings)

Use Atom as input to read_term/2 using the option variable_names and return the read term in Term and the variable bindings in Bindings. Bindings is a list of Name = Var couples, thus providing access to the actual variable names. See also read_term/2. If Atom has no valid syntax, a syntax_error exception is raised.

atom_concat(?Atom1, ?Atom2, ?Atom3)

Atom3 forms the concatenation of Atom1 and Atom2. At least two of the arguments must be instantiated to atoms, integers or floating point numbers. For ISO compliance, the instantiation-pattern -, -, + is allowed too, non-deterministically splitting the 3-th argument into two parts (as append/3 does for lists). See also string_concat/3.

concat_atom(+List, -Atom)

List is a list of atoms, integers or floating point numbers. Succeeds if Atom can be unified with the concatenated elements of List. If List has exactly 2 elements it is equivalent to atom_concat/3, allowing for variables in the list.

concat_atom(?List, +Separator, ?Atom)

Creates an atom just like concat_atom/2, but inserts Separator between each pair of atoms. For example:

?- concat_atom([gnu, gnat], ",", A).

A = 'gnu, gnat'

This predicate can also be used to split atoms by instantiating Separator and Atom:
4.22. CHARACTER PROPERTIES

?- concat_atom(L, -, 'gnu-gnat').
L = [gnu, gnat]

atom_length(+Atom, -Length)  [ISO]
True if Atom is an atom of Length characters long. This predicate also works for strings (see section 4.23). If the prolog flag iso is not set, it also accepts integers and floats, expressing the number of characters output when given to write/1 as well as code-lists and character-lists, expressing the length of the list.\(^{37}\)

atom_prefix(+Atom, +Prefix)
True if Atom starts with the characters from Prefix. Its behaviour is equivalent to
?- sub_atom(Atom, 0, _, _, Prefix). Depreciated.

ISO predicate for breaking atoms. It maintains the following relation: Sub is a sub-atom of Atom that starts at Before, has Len characters and Atom contains After characters after the match.

?- sub_atom(abc, 1, 1, A, S).
A = 1, S = b

The implementation minimises non-determinism and creation of atoms. This is a very flexible predicate that can do search, prefix- and suffix-matching, etc.

4.22 Character properties

SWI-Prolog offers two comprehensive predicates for classifying characters and character-codes. These predicates are defined as built-in predicates to exploit the C-character classification’s handling of locale (handling of local character-sets). These predicates are fast, logical and deterministic if applicable.

In addition, there is the library ctype providing compatibility to some other Prolog systems. The predicates of this library are defined in terms of code_type/2.

char_type(?Char, ?Type)
Tests or generates alternative Types or Chars. The character-types are inspired by the standard C <ctype.h> primitives.

alnum
Char is a letter (upper- or lowercase) or digit.

alpha
Char is a letter (upper- or lowercase).

\(^{37}\)BUG: Note that [] is both an atom an empty code/character list. The predicate atom_length/2 returns 2 for this atom.
csym
  \textit{Char} is a letter (upper- or lowercase), digit or the underscore (_). These are valid C- and Prolog symbol characters.

csymf
  \textit{Char} is a letter (upper- or lowercase) or the underscore (_). These are valid first characters for C- and Prolog symbols.

ascii
  \textit{Char} is a 7-bits ASCII character (0..127).

white
  \textit{Char} is a space or tab. E.i. white space inside a line.

cntrl
  \textit{Char} is an ASCII control-character (0..31).

digit
  \textit{Char} is a digit.

digit(\textit{Weight})
  \textit{Char} is a digit with value \textit{Weight}. I.e. \texttt{char_type(X, digit(6)} yields \texttt{X = ’6’}. Useful for parsing numbers.

xdigit(\textit{Weight})
  \textit{Char} is a hexa-decimal digit with value \textit{Weight}. I.e. \texttt{char_type(a, xdigit(X)} yields \texttt{X = ’10’}. Useful for parsing numbers.

graph
  \textit{Char} produces a visible mark on a page when printed. Note that the space is not included!

lower
  \textit{Char} is a lower-case letter.

lower(\textit{Upper})
  \textit{Char} is a lower-case version of \textit{Upper}. Only true if \textit{Char} is lowercase and \textit{Upper} uppercase.

to_lower(\textit{Upper})
  \textit{Char} is a lower-case version of \textit{Upper}. For non-letters, or letter without case, \textit{Char} and \textit{Lower} are the same. See also \texttt{upcase_atom/2} and \texttt{downcase_atom/2}.

upper
  \textit{Char} is an upper-case letter.

upper(\textit{Lower})
  \textit{Char} is an upper-case version of \textit{Lower}. Only true if \textit{Char} is uppercase and \textit{Lower} lowercase.

to_upper(\textit{Lower})
  \textit{Char} is an upper-case version of \textit{Lower}. For non-letters, or letter without case, \textit{Char} and \textit{Lower} are the same. See also \texttt{upcase_atom/2} and \texttt{downcase_atom/2}.

punct
  \textit{Char} is a punctuation character. This is a graph character that is not a letter or digit.

space
  \textit{Char} is some form of layout character (tab, vertical-tab, newline, etc.).
4.22. CHARACTER PROPERTIES

end_of_file
Char is -1.

end_of_line
Char ends a line (ASCII: 10..13).

newline
Char is a the newline character (10).

period
Char counts as the end of a sentence (., !, ?).

quote
Char is a quote-character (" ', ").

paren(Close)
Char is an open-parenthesis and Close is the corresponding close-parenthesis.

code_type(?Code, ?Type)
As char_type/2, but uses character-codes rather than one-character atoms. Please note
that both predicates are as flexible as possible. They handle either representation if the
argument is instantiated and only will instantiate with an integer code or one-character atom
depending of the version used. See also the Prolog flag double_quotes, atom_chars/2
and atom_codes/2.

4.22.1 Case conversion

There is nothing in the Prolog standard for converting case in textual data. The SWI-Prolog predicates
code_type/2 and char_type/2 can be used to test and convert individual characters. We have
started some additional support:

downcase_atom(+AnyCase, -LowerCase)
Converts the characters of AnyCase into lowercase as char_type/2 does (i.e. based on
the defined locale if Prolog provides locale support on the hosting platform) and unifies the
lowercase atom with LowerCase.

upcase_atom(+AnyCase, -UpperCase)
Converts, similar to downcase_atom/2, an atom to upper-case.

4.22.2 White space normalization

normalize_space(-Out, +In)
Normalize white space in In. All leading and trailing white space is removed. All non-empty
sequences for Unicode white space characters are replaces by a single space (\u0020) character. Out uses the same conventions as with_output_to/2 and format/3.

4.22.3 Language specific comparison

This section deals with predicates for language specific string comparison operations.

collation_key(+Atom, -Key)
Create a Key from Atom for locale specific comparison. The key is defined such that if the
key of atom \( A \) precedes the key of atom \( B \) in the standard order of terms, \( A \) is alphabetically smaller than \( B \) using the sort order of the current locale.

The predicate \texttt{collation_key/2} is used by \texttt{locale_sort/2} from library(sort). Please examine the implementation of \texttt{locale_sort/2} as an example of using this call.

The \textit{Key} is an implementation defined and generally unreadable string. On systems that do not support locale-handling, \textit{Key} is simply unified with \textit{Atom}.

\texttt{locale_sort(+List, -Sorted)}

Sort a list of atoms using the current locale. \textit{List} is a list of atoms or string objects (see section 4.23). \textit{Sorted} is unified with a list containing all atoms of \textit{List}, sorted to the rules of the current locale. See also \texttt{collation_key/2} and \texttt{setlocale/3}.

### 4.23 Representing text in strings

SWI-Prolog supports the data type \textit{string}. Strings are a time and space efficient mechanism to handle text in Prolog. Strings are stored as a byte array on the global (term) stack and thus destroyed on backtracking and reclaimed by the garbage collector.

Strings were added to SWI-Prolog based on an early draft of the ISO standard, offering a mechanism to represent temporary character data efficiently. As SWI-Prolog strings can handle 0-bytes, they are frequently used through the foreign language interface (section 9) for storing arbitrary byte-sequences.

Starting with version 3.3, SWI-Prolog offers garbage collection on the atom-space as well as representing 0-bytes in atoms. Although strings and atoms still have different features, new code should consider using atoms to avoid too many representations for text as well as for compatibility to other Prolog implementations. Below are some of the differences:

- **creation**
  Creating strings is fast, as the data is simply copied to the global stack. Atoms are unique and therefore more expensive in terms of memory and time to create. On the other hand, if the same text has to be represented multiple times, atoms are more efficient.

- **destruction**
  Backtracking destroys strings at no cost. They are cheap to handle by the garbage collector, but it should be noted that extensive use of strings will cause many garbage collections. Atom garbage collection is generally faster.

String objects by default have no lexical representation and thus can only be created using the predicates below or through the foreign language interface (See chapter 9. There are two ways to make \texttt{read/1} read text into strings, both controlled through Prolog flags. One is by setting the \texttt{double_quotes} flag to \texttt{string} and the other is by setting the \texttt{backquoted_string} flag to \texttt{true}. In latter case, 'Hello world' is read into a string and \texttt{write_term/2} prints strings between back-quotes if \texttt{quoted} is \texttt{true}. This flag provides compatibility to LPA Prolog string handling.

\texttt{string_to_atom(?String, ?Atom)}

Logical conversion between a string and an atom. At least one of the two arguments must be instantiated. \textit{Atom} can also be an integer or floating point number.
4.24. OPERATORS

string_to_list(?String, ?List)
Logical conversion between a string and a list of character codes characters. At least one of the two arguments must be instantiated.

string_length(+String, -Length)
Unify Length with the number of characters in String. This predicate is functionally equivalent to atom_length/2 and also accepts atoms, integers and floats as its first argument.

string_concat(?String1, ?String2, ?String3)
Similar to atom_concat/3, but the unbound argument will be unified with a string object rather than an atom. Also, if both String1 and String2 are unbound and String3 is bound to text, it breaks String3, unifying the start with String1 and the end with String2 as append does with lists. Note that this is not particularly fast on long strings as for each redo the system has to create two entirely new strings, while the list equivalent only creates a single new list-cell and moves some pointers around.

sub_string(+String, ?Start, ?Length, ?After, ?Sub)
Sub is a substring of String starting at Start, with length Length and String has After characters left after the match. See also sub_atom/5.

4.24 Operators

Operators are defined to improve the readability of source-code. For example, without operators, to write $2*3+4*5$ one would have to write $+(\times(2,3),\times(4,5))$. In Prolog, a number of operators have been predefined. All operators, except for the comma (,) can be redefined by the user.

Some care has to be taken before defining new operators. Defining too many operators might make your source ‘natural’ looking, but at the same time lead to hard to understand the limits of your syntax. To ease the pain, as of SWI-Prolog 3.3.0, operators are local to the module in which they are defined. Operators can be exported from modules using a term op(Precedence, Type, Name) in the export list as specified by module/2. This is an extension specific to SWI-Prolog and the advised mechanism of portability is not an important concern.

The module-table of the module user acts as default table for all modules and can be modified explicitly from inside a module to achieve compatibility to other Prolog systems:

```prolog
:- module(prove, [ prove/1 ]).
:- op(900, xfx, user:(=>)).
```

Unlike what many users think, operators and quoted atoms have no relation: defining an atom as an operator does not influence parsing characters into atoms and quoting an atom does not stop it from acting as an operator. To stop an atom acting as an operator, enclose it in braces like this: (myop).

op(+Precedence, +Type, :Name) [ISO]
Declare Name to be an operator of type Type with precedence Precedence. Name can also be a list of names, in which case all elements of the list are declared to be identical operators. Precedence is an integer between 0 and 1200. Precedence 0 removes the declaration. Type is
one of: $xf$, $yf$, $xfx$, $xfy$, $yfx$, $yfy$ or $fy$. The ‘$f$’ indicates the position of the functor, while $x$ and $y$ indicate the position of the arguments. ‘$y$’ should be interpreted as “on this position a term with precedence lower or equal to the precedence of the functor should occur”. For ‘$x$’ the precedence of the argument must be strictly lower. The precedence of a term is 0, unless its principal functor is an operator, in which case the precedence is the precedence of this operator. A term enclosed in brackets (…) has precedence 0.

The predefined operators are shown in table 4.1. Note that although all operators can be redefined by the user, this is strongly discouraged as it often leads to syntax errors or even different semantic interpretations when loading system libraries. It is advised to keep operators local to modules and load the system modules you need before changing operators.

**current_op(?Precedence, ?Type, ?:Name)**  
True if Name is currently defined as an operator of type Type with precedence Precedence. See also op/3.

### 4.25 Character Conversion

Although I wouldn’t really know for what you would like to use these features, they are provided for ISO compliance.

**char_conversion(+CharIn, +CharOut)**  
Define that term-input (see read_term/3) maps each character read as CharIn to the character CharOut. Character conversion is only executed if the Prolog flag char_conversion is

---

Table 4.1: System operators

| 1200 | $xf$ | -->, :- |
| 1200 | $fx$ | :-?, ?- |
| 1150 | $fx$ dynamic, discontiguous, initialization, module_transparent, multifile, thread_local, volatile |
| 1100 | $xy$ | ;, ! |
| 1050 | $xy$ | ->, op*-> |
| 1000 | $xy$ | , |
| 900  | $fy$ | \+ |
| 900  | $fx$ | - |
| 700  | $xfx$ | <, =, .., =@=, =:=, =\=, >, >=, @<, @=<, @>, @>= |
| 600  | $xy$ | : |
| 500  | $yfx$ | +, -, /\, \/, xor |
| 500  | $fx$ | ? |
| 400  | $yfx$ | *, //, rdiv, <>, mod, rem |
| 200  | $xf$ | ** |
| 200  | $xy$ | - |
| 200  | $fy$ | +, -, \ |
set to true and not inside quoted atoms or strings. The initial table maps each character onto itself. See also current_char_conversion/2.

**current_char_conversion(?CharIn, ?CharOut)**

Queries the current character conversion-table. See char_conversion/2 for details.

### 4.26 Arithmetic

Arithmetic can be divided into some special purpose integer predicates and a series of general predicates for integer, floating point and rational arithmetic as appropriate. The general arithmetic predicates all handle expressions. An expression is either a simple number or a function. The arguments of a function are expressions. The functions are described in section 4.26.2.

#### 4.26.1 Special purpose integer arithmetic

The predicates in this section provide more logical operations between integers. They are not covered by the ISO standard, although they are ‘part of the community’ and found as either library or built-in in many other Prolog systems.

**between(+Low, +High, ?Value)**

Low and High are integers, High ≥ Low. If Value is an integer, Low ≤ Value ≤ High. When Value is a variable it is successively bound to all integers between Low and High. If High is inf or infinite \(^{38}\) between/3 is true iff Value ≥ Low, a feature that is particularly interesting for generating integers from a certain value.

**succ(?Int1, ?Int2)**

True if Int2 = Int1 + 1 and Int1 ≥ 0. At least one of the arguments must be instantiated to a natural number. This predicate raises the domain-error not_less_than_zero if called with a negative integer. E.g. succ(X, 0) fails silently and succ(X, -1) raises a domain-error.\(^ {39}\)

**plus(?Int1, ?Int2, ?Int3)**

True if Int3 = Int1 + Int2. At least two of the three arguments must be instantiated to integers.

#### 4.26.2 General purpose arithmetic

The general arithmetic predicates are optionally compiled (see set_prolog_flag/2 and the -O command line option). Compiled arithmetic reduces global stack requirements and improves performance. Unfortunately compiled arithmetic cannot be traced, which is why it is optional.

**+Expr1 > +Expr2**  
True if expression Expr1 evaluates to a larger number than Expr2. \(^ {ISO}\)

**+Expr1 < +Expr2**  
True if expression Expr1 evaluates to a smaller number than Expr2. \(^ {ISO}\)

---

\(^{38}\)We prefer infinite, but some other Prolog systems already use inf for infinity we accept both for the time being.

\(^{39}\)The behaviour to deal with natural numbers only was defined by Richard O’Keefe to support the common count-down-to-zero in a natural way. Up-to 5.1.8 succ/2 also accepted negative integers.
+Expr1 =< +Expr2
  True if expression Expr1 evaluates to a smaller or equal number to Expr2.

+Expr1 >= +Expr2
  True if expression Expr1 evaluates to a larger or equal number to Expr2.

+Expr1 =
= +Expr2
  True if expression Expr1 evaluates to a number non-equal to Expr2.

+Expr1 =:= +Expr2
  True if expression Expr1 evaluates to a number equal to Expr2.

-Number is +Expr
  True if Number has successfully been unified with the number Expr evaluates to. If Expr
evaluates to a float that can be represented using an integer (i.e., the value is integer and within
the range that can be described by Prolog’s integer representation), Expr is unified with the
integer value.

Note that normally, is/2 should be used with unbound left operand. If equality is to be tested,
=:=/2 should be used. For example:

?- 1 is sin(pi/2).  Fails!. sin(pi/2) evaluates to the float 1.0,
which does not unify with the integer 1.
?- 1 =:= sin(pi/2).  Succeeds as expected.

Arithmetic types

SWI-Prolog defines the following numeric types:

- integer
  If SWI-Prolog is built using the GNU multiple precision arithmetic library (GMP), integer
  arithmetic is unbounded, which means that the size of integers is limited by available memory
  only. Without GMP, SWI-Prolog integers are 64-bits, regardless of the native integer size of
  the platform. The type of integer support can be detected using the Prolog flags bounded,
  min_integer and max_integer. As the use of GMP is default, most of the following
descriptions assume unbounded integer arithmetic.

  Internally, SWI-Prolog has three integer representations. Small integers (defined by the Prolog
  flag max_tagged_integer) are encoded directly. Larger integers are represented as 64-bit
  value on the global stack. Integers that do not fit in 64-bit are represented as serialised GNU
  MPZ structures on the global stack.

- rational number
  Rational numbers (Q) are quotients of two integers. Rational arithmetic is only provided if
  GMP is used (see above). Rational numbers are currently not supported by a Prolog type. They
  are represented by the compound term rdiv(N,M). Rational numbers that are returned from
  is/2 are canonical, which means M is positive and N and M have no common divisors. Ra-
  tional numbers are introduced in the computation using the rational/1, rationalize/1 or the
  rdiv/2 (rational division) function. Using the same functor for rational division and
  representing rational numbers allow for passing rational numbers between computations as well
  as to format/3 for printing.
On the long term it is likely that rational numbers will become atomic as well as subtype of number. User code that creates or inspects the \texttt{rdiv}(M,N) terms will not be portable to future versions. Rationals are created using one of the functions mentioned above and inspected using \texttt{rational}/3.

- \texttt{float}
  
  Floating point numbers are represented using the C-type \texttt{double}. On most today platforms these are 64-bit IEEE floating point numbers.

Arithmetic functions that require integer arguments accept, in addition to integers, rational numbers with denominator ‘1’ and floating point numbers that can be accurately converted to integers. If the required argument is a float the argument is converted to float. Note that conversion of integers to floating point numbers may raise an overflow exception. In all other cases, arguments are converted to the same type using the order below.

\begin{itemize}
  \item integer $\rightarrow$ rational number $\rightarrow$ floating point number
\end{itemize}

\textbf{Rational number examples}

The use of rational numbers with unbounded integers allows for exact integer or \textit{fixed point} arithmetic under the addition, subtraction, multiplication and division. To exploit rational arithmetic \texttt{rdiv}/2 should be used instead of ‘/’ and floating point numbers must be converted to rational using \texttt{rational}/1. Omitting the \texttt{rational}/1 on floats will convert a rational operand to float and continue the arithmetic using floating point numbers. Here are some examples.

\begin{itemize}
  \item A is 2 \texttt{rdiv} 6 \quad A = 1 \texttt{rdiv} 3
  \item A is 4 \texttt{rdiv} 3 + 1 \quad A = 7 \texttt{rdiv} 3
  \item A is 4 \texttt{rdiv} 3 + 1.5 \quad A = 2.83333
  \item A is 4 \texttt{rdiv} 3 + \texttt{rational}(1.5) \quad A = 17 \texttt{rdiv} 6
\end{itemize}

Note that floats cannot represent all decimal numbers exactly. The function \texttt{rational}/1 creates an \textit{exact} equivalent of the float, while \texttt{rationalize}/1 creates a rational number that is within the float rounding error from the original float. Please check the documentation of these functions for details and examples.

Rational numbers can be printed as decimal numbers with arbitrary precision using the \texttt{format}/3 floating point conversion:

\begin{verbatim}
?- A is 4 \texttt{rdiv} 3 + \texttt{rational}(1.5),
    format(’\^50f\^n’, [A]).
2.83333333333333333333333333333333333333333333333333
A = 17 \texttt{rdiv} 6
\end{verbatim}

\textbf{Arithmetic Functions}

Arithmetic functions are terms which are evaluated by the arithmetic predicates described in section 4.26.2. SWI-Prolog tries to hide the difference between integer arithmetic and floating point
arithmetic from the Prolog user. Arithmetic is done as integer arithmetic as long as possible and con-
verted to floating point arithmetic whenever one of the arguments or the combination of them requires
it. If a function returns a floating point value which is whole it is automatically transformed into an
integer. There are four types of arguments to functions:

- **Expr** Arbitrary expression, returning either a floating point value or an
  integer.
- **IntExpr** Arbitrary expression that must evaluate into an integer.
- **RatExpr** Arbitrary expression that must evaluate into a rational number.
- **FloatExpr** Arbitrary expression that must evaluate into a floating point.

For systems using bounded integer arithmetic (default is unbounded, see section 4.26.2 for de-
tails), integer operations that would cause overflow automatically convert to floating point arithmetic.

- `- +Expr`
  
  Result = -Expr

- `+ +Expr`
  
  Result = Expr. Note that if + is followed by a number the parser discards the +. I.e.
  `?- integer(+1)` succeeds.

- `+Expr1 + +Expr2`
  
  Result = Expr1 + Expr2

- `+Expr1 - +Expr2`
  
  Result = Expr1 - Expr2

- `+Expr1 * +Expr2`
  
  Result = Expr1 × Expr2

- `+Expr1 / +Expr2`
  
  The the flag iso is true, both arguments are converted to float and the
  return value is a float. Otherwise (default), if both arguments are integers the operation returns
  an integer if the division is exact. If at least one of the arguments is rational and the other
  argument is integer, the operation returns a rational number. In all other cases the return value
  is a float. See also `///2` and `rdiv/2`.

- `+IntExpr1 mod +IntExpr2`
  
  Modulo: Result = IntExpr1 - (IntExpr1 div IntExpr2) × IntExpr2, where div is floored di-
  vision.

- `+IntExpr1 rem +IntExpr2`
  
  Remainder of integer division. Behaves as if defined by
  Result is IntExpr1 - (IntExpr1 // IntExpr2) × IntExpr2

- `+IntExpr1 // +IntExpr2`
  
  Integer division: Result is truncate(Expr1/Expr2)

- `+RatExpr rdiv +RatExpr`
  
  Rational number division. This function is only available if SWI-Prolog has been compiled
  with rational number support. See section 4.26.2 for details.
abs(+Expr) [ISO]
Evaluate Expr and return the absolute value of it.

sign(+Expr) [ISO]
Evaluate to -1 if Expr < 0, 1 if Expr > 0 and 0 if Expr = 0.

max(+Expr1, +Expr2)
Evaluates to the largest of both Expr1 and Expr2. Both arguments are compared after converting to the same type, but the return value is in the original type. For example, max(2.5, 3) compares the two values after converting to float, but returns the integer 3.

min(+Expr1, +Expr2)
Evaluates to the smallest of both Expr1 and Expr2. See max/2 for a description of type-handling.

.(+Int, [])
A list of one element evaluates to the element. This implies "a" evaluates to the character code of the letter ‘a’ (97). This option is available for compatibility only. It will not work if ‘style_check(+string)’ is active as "a" will then be transformed into a string object. The recommended way to specify the character code of the letter ‘a’ is 0’a.

random(+IntExpr)
Evaluates to a random integer i for which 0 ≤ i < IntExpr. The seed of this random generator is determined by the system clock when SWI-Prolog was started.

round(+Expr) [ISO]
Evaluates Expr and rounds the result to the nearest integer.

integer(+Expr)
Same as round/1 (backward compatibility).

float(+Expr) [ISO]
Translate the result to a floating point number. Normally, Prolog will use integers whenever possible. When used around the 2nd argument of is/2, the result will be returned as a floating point number. In other contexts, the operation has no effect.

rational(+Expr)
Convert the Expr to a rational number or integer. The function returns the input on integers and rational numbers. For floating point numbers, the returned rational number exactly represents the float. As floats cannot exactly represent all decimal numbers the results may be surprising. In the examples below, doubles can represent 0.25 and the result is as expected, in contrast to the result of rational(0.1). The function rationalize/1 remedies this. See section 4.26.2 for more information on rational number support.

?- A is rational(0.25).
A is 1 rdiv 4
?- A is rational(0.1).
A = 3602879701896397 rdiv 36028797018963968
rationalize(+Expr)
Convert the Expr to a rational number or integer. The function is similar to rational/1, but the result is only accurate within the rounding error of floating point numbers, generally producing a much smaller denominator.\(^ {40} \)

?- A is rationalize(0.25).
A = 1 rdiv 4
?- A is rationalize(0.1).
A = 1 rdiv 10

float fraction_part(+Expr) \([\text{ISO}]\)
Fractional part of a floating-point number. Negative if Expr is negative, rational if Expr is rational and 0 if Expr is integer. The following relation is always true: \( X\text{isfloat\text{fractional\_part}}(X) + X\text{isfloat\text{integer\_part}}(X) \).  

float integer_part(+Expr) \([\text{ISO}]\)
Integer part of floating-point number. Negative if Expr is negative, Expr if Expr is integer.

truncate(+Expr) \([\text{ISO}]\)
Truncate Expr to an integer. If Expr \( \geq 0 \) this is the same as floor(Expr). For Expr \( < 0 \) this is the same as ceil(Expr). E.i. truncate rounds towards zero.

floor(+Expr) \([\text{ISO}]\)
Evaluates Expr and returns the largest integer smaller or equal to the result of the evaluation.

ceiling(+Expr) \([\text{ISO}]\)
Evaluates Expr and returns the smallest integer larger or equal to the result of the evaluation.

ceil(+Expr)
Same as ceiling/1 (backward compatibility).

\(+IntExpr\gg +IntExpr\) \([\text{ISO}]\)
Bitwise shift IntExpr1 by IntExpr2 bits to the right. The operation performs arithmetic shift, which implies that the inserted most significant bits are copies of the original most significant bit.

\(+IntExpr\ll +IntExpr\) \([\text{ISO}]\)
Bitwise shift IntExpr1 by IntExpr2 bits to the left.

\(+IntExpr\lor +IntExpr\) \([\text{ISO}]\)
Bitwise ‘or’ IntExpr1 and IntExpr2.

\(+IntExpr\land +IntExpr\) \([\text{ISO}]\)
Bitwise ‘and’ IntExpr1 and IntExpr2.

\(+IntExpr\xor +IntExpr\)
Bitwise ‘exclusive or’ IntExpr1 and IntExpr2.

\(^{40}\)The names rational/1 and rationalize/1 as well as their semantics are inspired by Common Lisp.
\(+\text{IntExpr}\)  
Bitwise negation. The returned value is the one’s complement of \text{IntExpr}.

\(\text{sqrt}(+\text{Expr})\)  
Result = \(\sqrt{\text{Expr}}\)  
[ISO]

\(\text{sin}(+\text{Expr})\)  
Result = \(\sin \text{Expr}\). \text{Expr} is the angle in radians.

\(\text{cos}(+\text{Expr})\)  
Result = \(\cos \text{Expr}\). \text{Expr} is the angle in radians.

\(\text{tan}(+\text{Expr})\)  
Result = \(\tan \text{Expr}\). \text{Expr} is the angle in radians.

\(\text{asin}(+\text{Expr})\)  
Result = \(\arcsin \text{Expr}\). Result is the angle in radians.

\(\text{acos}(+\text{Expr})\)  
Result = \(\arccos \text{Expr}\). Result is the angle in radians.

\(\text{atan}(+\text{Expr})\)  
Result = \(\arctan \text{Expr}\). Result is the angle in radians.

\(\text{atan}(+Y\text{Expr}, +X\text{Expr})\)  
Result = \(\arctan \frac{Y\text{Expr}}{X\text{Expr}}\). Result is the angle in radians. The return value is in the range \([-\pi . . . \pi]\). Used to convert between rectangular and polar coordinate system.

\(\text{log}(+\text{Expr})\)  
Natural logarithm. Result = \(\ln \text{Expr}\)

\(\text{log10}(+\text{Expr})\)  
Base-10 logarithm. Result = \(\lg \text{Expr}\)

\(\text{exp}(+\text{Expr})\)  
Result = \(e^\text{Expr}\)  
[ISO]

\(+\text{Expr1} \star\star +\text{Expr2}\)  
Result = \(\text{Expr1}^{\text{Expr2}}\). With unbounded integers and integer values for \text{Expr1} and a non-negative integer \text{Expr2}, the result is always integer. The integer expressions 0\(^I\), 1\(^I\) and \(-1\(^I\) are guaranteed to work for any integer \(I\). Other integer base values generate a resource error if the result does not fit in memory.

\(\text{powm}(+\text{IntExprBase}, +\text{IntExprExp}, +\text{IntExprMod})\)  
Result = \((\text{IntExprBase}^{\text{IntExprExp}}) \bmod \text{IntExprMod}\). Only available when compiled with unbounded integer support. This formula is required for Diffie-Hellman key-exchange, a technique where two parties can establish a secret key over a public network.

\(+\text{Expr1} \wedge +\text{Expr2}\)  
Same as **/#2. (backward compatibility).
pi
Evaluates to the mathematical constant $\pi$ (3.14159\ldots).

e
Evaluates to the mathematical constant $e$ (2.71828\ldots).

cputime
Evaluates to a floating point number expressing the CPU time (in seconds) used by Prolog up till now. See also statistics/2 and time/1.

eval(+Expr)
Evaluate $\texttt{Expr}$. Although ISO standard dictates that $A=1+2$, $B$ is $\texttt{A}$ works and unifies $B$ to 3, it is widely felt that source-level variables in arithmetic expressions should have been limited to numbers. In this view the eval function can be used to evaluate arbitrary expressions.\footnote{The eval/1 function was first introduced by ECLiPSe and is under consideration for YAP.}

Bitvector functions The functions below are not covered by the standard. The $\mathrm{msb}/1$ function is compatible to $\mathrm{hProlog}$. The others are private extensions that improve handling of —unbounded— integers as bit-vectors.

$\mathrm{msb}(+\texttt{IntExpr})$
Return the largest integer $N$ such that $(\texttt{IntExpr} \gg N) \land 1 =:= 1$. This is the (zero-origin) index of the most significant 1 bit in the value of $\texttt{IntExpr}$, which must evaluate to a positive integer. Errors for 0, negative integers, and non-integers.

$\mathrm{lsb}(+\texttt{IntExpr})$
Return the smallest integer $N$ such that $(\texttt{IntExpr} \gg N) \land 1 =:= 1$. This is the (zero-origin) index of the least significant 1 bit in the value of $\texttt{IntExpr}$, which must evaluate to a positive integer. Errors for 0, negative integers, and non-integers.

$\mathrm{popcount}(+\texttt{IntExpr})$
Return the number of 1s in the binary representation of the non-negative integer $\texttt{IntExpr}$.

4.27 Adding Arithmetic Functions

Prolog predicates can be given the role of arithmetic function. The last argument is used to return the result, the arguments before the last are the inputs. Arithmetic functions are added using the predicate $\mathrm{arithmetic\_function}/1$, which takes the head as its argument. Arithmetic functions are module sensitive, that is they are only visible from the module in which the function is defined and declared. Global arithmetic functions should be defined and registered from module $\texttt{user}$. Global definitions can be overruled locally in modules. The built-in functions described above can be redefined as well.

$\mathrm{arithmetic\_function}(+\texttt{Head})$
Register a Prolog predicate as an arithmetic function (see $\mathrm{is}/2$, $\mathrm{>/2}$, etc.). The Prolog predicate should have one more argument than specified by $\texttt{Head}$, which it either a term $\texttt{Name/Arity}$, an atom or a complex term. This last argument is an unbound variable at call time and should be instantiated to an integer or floating point number. The other arguments are the parameters.
This predicate is module sensitive and will declare the arithmetic function only for the context module, unless declared from module user. Example:

```prolog
1 ?- [user].
    :- arithmetic_function(mean/2).

mean(A, B, C) :-
    C is (A+B)/2.
user compiled, 0.07 sec, 440 bytes.

Yes
2 ?- A is mean(4, 5).
A = 4.500000
```

**current_arithmetic_function(?Head)**

Successively unifies all arithmetic functions that are visible from the context module with Head.

### 4.28 Built-in list operations

Most list operations are defined in the library lists described in section A.11. Some that are implemented with more low-level primitives are built-in and described here.

**is_list(+Term)**

True if Term is bound to the empty list ([ ]) or a term with functor `.` and arity 2 and the second argument is a list. This predicate acts as if defined by the definition below on acyclic terms. The implementation is fails safely if Term represents a cyclic list.

```prolog
is_list(X) :-
    var(X), !,
    fail.
is_list([]).
is_list([_|T]) :-
    is_list(T).
```

**memberchk(?Elem, +List)**

Equivalent to member/2, but leaves no choice point.

**length(?List, ?Int)**

True if Int represents the number of elements of list List. Can be used to create a list holding only variables.

---

42In versions before 5.0.1, is_list/1 just checked for [] or [_|_] and proper_list/1 had the role of the current is_list/1. The current definition is conform the de-facto standard. Assuming proper coding standards, there should only be very few cases where a quick-and-dirty is_list/1 is a good choice. Richard O'Keefe pointed at this issue.
sort(+List, -Sorted)
   True if Sorted can be unified with a list holding the elements of List, sorted to the standard order of terms (see section 4.6). Duplicates are removed. The implementation is in C, using natural merge sort.\(^\text{43}\) The sort/2 predicate can sort a cyclic list, returning a non-cyclic version with the same elements.

msort(+List, -Sorted)
   Equivalent to sort/2, but does not remove duplicates. Fails with a type_error if List is not a list or a cyclic list.

depsort(+Pred, +List, -Sorted)
   Sorts similar to sort/2, but determines the order of two terms by calling Pred(-Delta, +E1, +E2). This call must unify Delta with one of <?, > or =. If built-in predicate compare/3 is used, the result is the same as sort/2. See also keysort/2.\(^\text{44}\)

merge(+List1, +List2, -List3)
   List1 and List2 are lists, sorted to the standard order of terms (see section 4.6). List3 will be unified with an ordered list holding both the elements of List1 and List2. Duplicates are not removed.

merge_set(+Set1, +Set2, -Set3)
   Set1 and Set2 are lists without duplicates, sorted to the standard order of terms. Set3 is unified with an ordered list without duplicates holding the union of the elements of Set1 and Set2.

### 4.29 Finding all Solutions to a Goal

findall(+Template, :Goal, -Bag)
   Creates a list of the instantiations Template gets successively on backtracking over Goal and unifies the result with Bag. Succeeds with an empty list if Goal has no solutions. findall/3 is equivalent to bagof/3 with all free variables bound with the existential operator (\(^\hat{\text{\_}}\)), except that bagof/3 fails when goal has no solutions.

findall(+Template, :Goal, -Bag, +Tail)
   As findall/2, but returns the result as the difference-list Bag-Tail. The 3-argument version is defined as

\(^{43}\)Contributed by Richard O’Keefe.
\(^{44}\)Please note that the semantics have changed between 3.1.1 and 3.1.2
4.30 Invoking Predicates on all Members of a List

All the predicates in this section call a predicate on all members of a list or until the predicate called fails. The predicate is called via call/[2..], which implies common arguments can be put in front of the arguments obtained from the list(s). For example:
?- maplist(plus(1), [0, 1, 2], X).
X = [1, 2, 3]

we phrase this as “Predicate is applied on . . . ”

Currently, the predicates below are defined as built-in predicates. It is planned to move these to library(apply). See section A.2 for more predicates. The library(apply_macros) defines macros that compile some of these meta-calling constructs away.

maplist(\(\text{Pred}, +\text{List}\))
\(\text{Pred}\) is applied successively on each element of \(\text{List}\) until the end of the list or \(\text{Pred}\) fails. In the latter case the maplist/2 fails.\(^{45}\)

maplist(\(\text{Pred}, ?\text{List1}, ?\text{List2}\))
Apply \(\text{Pred}\) on all successive pairs of elements from \(\text{List1}\) and \(\text{List2}\). Fails if \(\text{Pred}\) can not be applied to a pair. See the example above.

maplist(\(\text{Pred}, ?\text{List1}, ?\text{List2}, ?\text{List3}\))
Apply \(\text{Pred}\) on all successive triples of elements from \(\text{List1}, \text{List2}\) and \(\text{List3}\). Fails if \(\text{Pred}\) can not be applied to a triple. See the example above.

4.31 Forall

forall(\(\text{Cond}, :\text{Action}\)) \[\text{[semidet]}\]
For all alternative bindings of \(\text{Cond}\) \(\text{Action}\) can be proven. The example verifies that all arithmetic statements in the list \(L\) are correct. It does not say which is wrong if one proves wrong.

?- forall(member(Result = Formula, [2 = 1 + 1, 4 = 2 * 2]),
Result =:= Formula).

4.32 Formatted Write

The current version of SWI-Prolog provides two formatted write predicates. The first is writef/[1,2], which is compatible with Edinburgh C-Prolog. The second is format/[1,2], which is compatible with Quintus Prolog. We hope the Prolog community will once define a standard formatted write predicate. If you want performance use format/[1,2] as this predicate is defined in C. Otherwise compatibility reasons might tell you which predicate to use.

4.32.1 Writef

writeln(+Term)
Equivalent to write(Term), nl.

writef(+Atom)
Equivalent to writef(Atom, []).\(^{45}\)

\(^{45}\)The maplist/2 predicate replaces the obsolete checklist/2 predicate.
writef(+Format, +Arguments)

Formatted write. \textit{Format} is an atom whose characters will be printed. \textit{Format} may contain certain special character sequences which specify certain formatting and substitution actions. \textit{Arguments} then provides all the terms required to be output.

Escape sequences to generate a single special character:

<table>
<thead>
<tr>
<th>Escape</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\n</td>
<td>Output a newline character (see also \nl/[0,1])</td>
</tr>
<tr>
<td>\l</td>
<td>Output a line separator (same as \n)</td>
</tr>
<tr>
<td>\r</td>
<td>Output a carriage-return character (ASCII 13)</td>
</tr>
<tr>
<td>\t</td>
<td>Output the ASCII character TAB (9)</td>
</tr>
<tr>
<td>\</td>
<td>The character \ is output</td>
</tr>
<tr>
<td>%</td>
<td>The character % is output</td>
</tr>
<tr>
<td>\nnn</td>
<td>where \langle nnn \rangle is an integer (1-3 digits) the character with character code \langle nnn \rangle is output (NB: \langle nnn \rangle is read as \textit{decimal})</td>
</tr>
</tbody>
</table>

Note that \l, \nnn and \\ are interpreted differently when character-escapes are in effect. See section 2.15.1.

Escape sequences to include arguments from \textit{Arguments}. Each time a % escape sequence is found in \textit{Format} the next argument from \textit{Arguments} is formatted according to the specification.

| %t  | \texttt{print/1} the next item (mnemonic: term) |
| %w  | \texttt{write/1} the next item |
| %q  | \texttt{writeq/1} the next item |
| %d  | Write the term, ignoring operators. See also \texttt{write_term/2}. Mnemonic: old Edinburgh display/1. |
| %p  | \texttt{print/1} the next item (identical to \%t) |
| %n  | Put the next item as a character (i.e., it is a character code) |
| %r  | Write the next item N times where N is the second item (an integer) |
| %s  | Write the next item as a String (so it must be a list of characters) |
| %f  | Perform a \texttt{ttyflush/0} (no items used) |
| %Nc | Write the next item Centered in N columns. |
| %Nl | Write the next item Left justified in N columns. |
| %Nr | Write the next item Right justified in N columns. N is a decimal number with at least one digit. The item must be an atom, integer, float or string. |

swritef(-String, +Format, +Arguments)

Equivalent to \texttt{writef/2}, but “writes” the result on \texttt{String} instead of the current output stream.

Example:
?- swritef(S, '%15L%w', ['Hello', 'World']).

S = "Hello             World"

swritef(-String, +Format)
Equivalent to swritef(String, Format, []).

4.32.2 Format

format(+Format)
Defined as ‘format(Format) :- format(Format, []).’

format(+Format, +Arguments)
Format is an atom, list of character codes, or a Prolog string. Arguments provides the arguments required by the format specification. If only one argument is required and this is not a list of character codes the argument need not be put in a list. Otherwise the arguments are put in a list.

Special sequences start with the tilde (~), followed by an optional numeric argument, followed by a character describing the action to be undertaken. A numeric argument is either a sequence of digits, representing a positive decimal number, a sequence \(\langle\text{character}\rangle\), representing the character code value of the character (only useful for \(\sim t\)) or a asterisk (*), in when the numeric argument is taken from the next argument of the argument list, which should be a positive integer.

Numeric conversion (d, D, e, E, f, g and G) accept an arithmetic expression as argument. This is introduced to handle rational numbers transparently (see section 4.26.2. The floating point conversions allow for unlimited precision for printing rational numbers in decimal form.

\sim Output the tilde itself.
\a Output the next argument, which must be an atom. This option is equivalent to w, except for that it requires the argument to be an atom.
\c Interpret the next argument as an character code and add it to the output. This argument should be an integer in the range \([0, \ldots, 255]\) (including 0 and 255).
\d Output next argument as a decimal number. It should be an integer. If a numeric argument is specified a dot is inserted argument positions from the right (useful for doing fixed point arithmetic with integers, such as handling amounts of money).
\D Same as \d, but makes large values easier to read by inserting a comma every three digits left to the dot or right.
\e Output next argument as a floating point number in exponential notation. The numeric argument specifies the precision. Default is 6 digits. Exact representation depends on the C library function printf(). This function is invoked with the format \texttt{%}.\langle\text{precision}\rangle\texttt{e}.
\E Equivalent to \e, but outputs a capital E to indicate the exponent.
\f Floating point in non-exponential notation. See C library function printf().
\g Floating point in \e or \f notation, whichever is shorter.
\G Floating point in \E or \f notation, whichever is shorter.
\i Ignore next argument of the argument list. Produces no output.
k Give the next argument to (write_canonical/1).

n Output a newline character.

N Only output a newline if the last character output on this stream was not a newline. Not properly implemented yet.

p Give the next argument to print/1.

q Give the next argument to writeq/1.

r Print integer in radix the numeric argument notation. Thus ^16r prints its argument hexadecimal. The argument should be in the range [2, . . . , 36]. Lower case letters are used for digits above 9.

R Same as r, but uses upper case letters for digits above 9.

s Output text from a list of character codes or a string (see string/1 and section 4.23) from the next argument.

@ Interpret the next argument as a goal and execute it. Output written to the current_output stream is inserted at this place. Goal is called in the module calling format/3. This option is not present in the original definition by Quintus, but supported by some other Prolog systems.

t All remaining space between 2 tab stops is distributed equally over ^t statements between the tab stops. This space is padded with spaces by default. If an argument is supplied this is taken to be the character code of the character used for padding. This can be used to do left or right alignment, centering, distributing, etc. See also ^| and ^+ to set tab stops. A tab stop is assumed at the start of each line.

| Set a tab stop on the current position. If an argument is supplied set a tab stop on the position of that argument. This will cause all ^t’s to be distributed between the previous and this tab stop.

+ Set a tab stop relative to the current position. Further the same as ^|.

w Give the next argument to write/1.

W Give the next two argument to write_term/2. E.g. format (^W", [Term, [numbervars(true)])]. This option is SWI-Prolog specific.

Example:

simple_statistics :-
<obtain statistics> % left to the user
format(^tStatistics^t72|^n^n’),
format(^Runtime: ^t^2f^34| Inferences: ^t^D^72|^n’,
      [RunT, Inf]),
....

Will output

Statistics

Runtime: .................. 3.45 Inferences: ............ 60,345
format(+Output, +Format, +Arguments)
   As format/2, but write the output on the given Output. The de-facto standard only allows Output to be a stream. The SWI-Prolog implementation allows all valid arguments for with_output_to/2. For example:

    ?- format(atom(A), '˜D', [1000000]).
   A = '1,000,000'

4.32.3 Programming Format

format_predicate(+Char, +Head)
   If a sequence `c (tilde, followed by some character) is found, the format derivatives will first check whether the user has defined a predicate to handle the format. If not, the built in formatting rules described above are used. Char is either an ASCII value, or a one character atom, specifying the letter to be (re)defined. Head is a term, whose name and arity are used to determine the predicate to call for the redefined formatting character. The first argument to the predicate is the numeric argument of the format command, or the atom default if no argument is specified. The remaining arguments are filled from the argument list. The example below redefines `n to produce Arg times return followed by linefeed (so a (Grr.) DOS machine is happy with the output).

    :- format_predicate(n, dos_newline(_Arg)).

dos_newline(default) :- !,
                   dos_newline(1).

dos_newline(N) :-
   ( N > 0 -> write('\r\n'),
     N2 is N - 1,
     dos_newline(N2)
   ; true
).

current_format_predicate(?Code, :Head)
   Enumerates all user-defined format predicates. Code is the character code of the format character. Head is unified with a term with the same name and arity as the predicate. If the predicate does not reside in module user, Head is qualified with the definition module of the predicate.

4.33 Terminal Control

The following predicates form a simple access mechanism to the Unix termcap library to provide terminal independent I/O for screen terminals. These predicates are only available on Unix machines. The SWI-Prolog Windows consoles accepts the ANSI escape sequences.

46Earlier versions defined sformat/3. These predicates have been moved to the library backcomp.
4.34. OPERATING SYSTEM INTERACTION

tty_get_capability(+Name, +Type, -Result)
Get the capability named Name from the termcap library. See termcap(5) for the capability names. Type specifies the type of the expected result, and is one of string, number or bool. String results are returned as an atom, number result as an integer and bool results as the atom on or off. If an option cannot be found this predicate fails silently. The results are only computed once. Successive queries on the same capability are fast.

tty_goto(+X, +Y)
Goto position (X, Y) on the screen. Note that the predicates line_count/2 and line_position/2 will not have a well defined behaviour while using this predicate.

tty_put(+Atom, +Lines)
Put an atom via the termcap library function tputs(). This function decodes padding information in the strings returned by tty_get_capability/3 and should be used to output these strings. Lines is the number of lines affected by the operation, or 1 if not applicable (as in almost all cases).

set_tty(-OldStream, +NewStream)
Set the output stream, used by tty_put/2 and tty_goto/2 to a specific stream. Default is user_output.

tty_size(-Rows, -Columns)
Determine the size of the terminal. Platforms:

Unix If the system provides ioctl calls for this, these are used and tty_size/2 properly reflects the actual size after a user resize of the window. As a fallback, the system uses tty_get_capability/3 using li and co capabilities. In this case the reported size reflects the size at the first call and is not updated after a user-initiated resize of the terminal.

Windows Getting the size of the terminal is provided for plwin.exe. The requested value reflects the current size. For the multi-threaded version the console that is associated with the user_input stream is used.

4.34 Operating System Interaction

shell(+Command, -Status)
Execute Command on the operating system. Command is given to the Bourne shell (/bin/sh). Status is unified with the exit status of the command.

On Win32 systems, shell/[1,2] executes the command using the CreateProcess() API and waits for the command to terminate. If the command ends with a & sign, the command is handed to the WinExec() API, which does not wait for the new task to terminate. See also win_exec/2 and win_shell/2. Please note that the CreateProcess() API does not imply the Windows command interpreter (command.exe on Windows 95/98 and cmd.exe on Windows-NT) and therefore commands built-in to the command-interpreter can only be activated using the command interpreter. For example: ‘command.exe /C copy file1.txt file2.txt’

shell(+Command)
Equivalent to ‘shell(Command, 0)’.
shell
Start an interactive Unix shell. Default is /bin/sh, the environment variable SHELL overrides this default. Not available for Win32 platforms.

`win_exec(+Command, +Show)`
Win32 systems only. Spawns a Windows task without waiting for its completion. `Show` is one of the Win32 SW_* constants written in lowercase without the SW_*: hide maximize minimize restore show showdefault showmaximized showminimized showminnoactive showna shownoactive shownormal. In addition, iconic is a synonym for minimize and normal for shownormal.

`win_shell(+Operation, +File, +Show)`
Win32 systems only. Opens the document `File` using the windows shell-rules for doing so. `Operation` is one of open, print or explore or another operation registered with the shell for the given document-type. On modern systems it is also possible to pass a URL as `File`, opening the URL in Windows default browser. This call interfaces to the Win32 API ShellExecute(). The `Show` argument determines the initial state of the opened window (if any). See `win_exec/2` for defined values.

`win_shell(+Operation, +File)`
Same as `win_shell(Operation, File, normal)`

`win_registry_get_value(+Key, +Name, -Value)`
Win32 systems only. Fetches the value of a Win32 registry key. `Key` is an atom formed as a path-name describing the desired registry key. `Name` is the desired attribute name of the key. `Value` is unified with the value. If the value is of type DWORD, the value is returned as an integer. If the value is a string it is returned as a Prolog atom. Other types are currently not supported. The default ‘root’ is HKEY_CURRENT_USER. Other roots can be specified explicitly as HKEY_CLASSES_ROOT, HKEY_CURRENT_USER, HKEY_LOCAL_MACHINE or HKEY_USERS. The example below fetches the extension to use for Prolog files (see README.TXT on the Windows version):

```
?- win_registry_get_value(’HKEY_LOCAL_MACHINE/Software/SWI/Prolog’,
                           fileExtension,
                           Ext).

Ext = pl
```

`win_folder(\Name, -Directory)`
Is true if `Name` is the Windows ‘CSIDL’ of `Directory`. If `Name` is unbound all known Windows special paths are generated. `Name` is the CSIDL after deleting the leading CSIDL and mapping the constant to lowercase. Check the Windows documentation for the function SHGetSpecialFolderPath() for a description of the defined constants. This example extracts the ‘My Documents’ folder:

```
?- win_folder(personal, MyDocuments).

MyDocuments = ’C:/Documents and Settings/jan/My Documents’
```
4.34. OPERATING SYSTEM INTERACTION

getenv(+Name, -Value)
Get environment variable. Fails silently if the variable does not exist. Please note that environment variable names are case-sensitive on Unix systems and case-insensitive on Windows.

setenv(+Name, +Value)
Set an environment variable. Name and Value must be instantiated to atoms or integers. The environment variable will be passed to shell/[0-2] and can be requested using getenv/2. They also influence expand_file_name/2. Environment variables are shared between threads. Depending on the underlying C library, setenv/2 and unsetenv/1 may not be thread-safe and may cause memory leaks. Only changing the environment once and before starting threads is safe in all versions of SWI-Prolog.

unsetenv(+Name)
Remove an environment variable from the environment. Some systems lack the underlying unsetenv() library function. On these systems unsetenv/1 sets the variable to the empty string.

setlocale(+Category, -Old, +New)
Set/Query the locale setting which tells the C-library how to interpret text-files, write numbers, dates, etc. Category is one of all, collate, ctype, messages, monetary, numeric or time. For details, please consult the C-library locale documentation. See also section 2.17.1. Please note that the locale is shared between all threads and thread-safe usage of setlocale/3 is in general not possible. Do locale operations before starting threads or thoroughly study threading aspects of locale support in your environment before use in multi-threaded environments. Locale settings are used by format_time/3, collation_key/2 and locale_sort/2.

unix(+Command)
This predicate comes from the Quintus compatibility library and provides a partial implementation thereof. It provides access to some operating system features and unlike the name suggests, is not operating system specific. Defined Command’s are below.

system(+Command)
Equivalent to calling shell/1. Use for compatibility only.

shell(+Command)
Equivalent to calling shell/1. Use for compatibility only.

shell
Equivalent to calling shell/0. Use for compatibility only.

cd
Equivalent to calling working_directory/2 to the expansion (see expand_file_name/2) of ~. For compatibility only.

cd(+Directory)
Equivalent to calling working_directory/2. Use for compatibility only.

argv(-Argv)
Unify Argv with the list of command-line arguments provides to this Prolog run. Please note that Prolog system-arguments and application arguments are separated by --. Integer arguments are passed as Prolog integers, float arguments and Prolog floating
point numbers and all other arguments as Prolog atoms. New applications should use the Prolog flag `argv`. See also prolog Prolog flag `argv`.

A stand-alone program could use the following skeleton to handle command-line arguments. See also section 2.10.2.

```
main :-
    current_prolog_flag(argv, Argv),
   append(_PrologArgs, [|--|AppArgs], Argv), !,
   main(AppArgs).
```

### 4.34.1 Dealing with time and date

Representing time in a computer system is surprisingly complicated. There are a large number of time representations in use and the correct choice depends on factors such as compactness, resolution and desired operations. Humans tend to think about time in hours, days, months, years or centuries. Physicists think about time in seconds. But, a month does not have a defined number of seconds. Even a day does not have a defined number of seconds as sometimes a leap-second is introduced to synchronise properly with our earth’s rotation. At the same time, resolution demands range from better then pico-seconds to millions of years. Finally, civilizations have a wide range of calendars. Although there exist libraries dealing with most if this complexity, our desire to keep Prolog clean and lean stops us from fully supporting these.

For human-oriented tasks, time can be broken into years, months, days, hours, minutes, seconds and a timezone. Physicists prefer to have time in an arithmetic type representing seconds or fraction thereof, so basic arithmetic deal with comparison and durations. An additional advantage of the physicists approach is that it requires much less space. For these reasons, SWI-Prolog uses an arithmetic type as its prime time representation.

Many C libraries deal with time using fixed-point arithmetic, dealing with a large but finite time interval at constant resolution. In our opinion using a floating point number is a more natural choice as we can use a natural unit and the interface does not need to be changed if a higher resolution is required in the future. Our unit of choice is the second as it is the scientific unit.\footnote{Using Julian days is a choice made by the Eclipse team. As conversion to dates is needed for a human readable notation of time and Julian days cannot deal naturally with leap seconds, we decided for second as our unit.} We have placed our origin at 1970-1-1T0:0:0Z for compatibility with the POSIX notion of time as well as with older time support provided by SWI-Prolog.

Where older versions of SWI-Prolog relied on the POSIX conversion functions, the current implementation uses libtai to realise conversion between time-stamps and calendar dates for a period of 10 million years.

**Time and date data-structures**

We use the following time representations

**TimeStamp**

A TimeStamp is a floating point number expression the time in seconds since the Epoch at 1970-1-1.
date(Y,M,D,H,Mn,S,Off,TZ,DST)
We call this term a date-time structure. The first 5 fields are integers expressing the year, month (1..12), day (1..31), hour (0..23), Minute (0..59). The S field holds the seconds as a floating point number between 0.0 and 60.0. Off is an integer representing the offset relative to UTC in seconds where positive values are west of Greenwich. If converted from local time (see stamp_date_time/3, TZ holds the name of the local timezone. If the timezone is not known TZ is the atom -. DST is true if daylight saving time applies to the current time, false if daylight saving time is relevant but not effective and - if unknown or the timezone has no daylight saving time.

date(Y,M,D)
Date using the same values as described above. Extracted using date_time_value/3.

time(H,Mn,S)
Time using the same values as described above. Extracted using date_time_value/3.

Time and date predicates

get_time(-TimeStamp)
Return the current time as a TimeStamp. The granularity is system dependent. See section 4.34.1.

stamp_date_time(+TimeStamp, -DateTime, +TimeZone)
Convert a TimeStamp to a DateTime in the given timezone. See section 4.34.1 for details on the data-types. TimeZone describes the timezone for the conversion. It is one of local to extract the local time, ‘UTC’ to extract at UTC time or an integer describing the seconds west of Greenwich.

date_time_stamp(+DateTime, -TimeStamp)
Compute the timestamp from a date/9 term. Values for month, day, hour, minute or second need not be normalized. This flexibility allows for easy computation of the time at any given number of these units from a given timestamp. Normalization can be achieved following this call with stamp_date_time/3. This example computes the date 200 days after 2006-7-14:

?- date_time_stamp(date(2006,7,214,0,0,0,0,-,-), Stamp),
   stamp_date_time(Stamp, D, 0),
   date_time_value(date, D, Date).
Date = date(2007, 1, 30)

date_time_value(?Key, +DateTime, ?Value)
Extract values from a date/9 term. Provided keys are:
### CHAPTER 4. BUILT-IN PREDICATES

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>Calendar year as an integer</td>
</tr>
<tr>
<td>month</td>
<td>Calendar month as an integer 1..12</td>
</tr>
<tr>
<td>day</td>
<td>Calendar day as an integer 1..31</td>
</tr>
<tr>
<td>hour</td>
<td>Clock hour as an integer 0..23</td>
</tr>
<tr>
<td>minute</td>
<td>Clock minute as an integer 0..59</td>
</tr>
<tr>
<td>second</td>
<td>Clock second as a float 0.0..60.0</td>
</tr>
<tr>
<td>utc_offset</td>
<td>Offset to UTC in seconds (positive is west)</td>
</tr>
<tr>
<td>time_zone</td>
<td>Name of timezone; fails if unknown</td>
</tr>
<tr>
<td>daylight_saving</td>
<td>Bool  (true) if dst is effective</td>
</tr>
<tr>
<td>date</td>
<td>Term date(Y,M,D)</td>
</tr>
<tr>
<td>time</td>
<td>Term time(H,M,S)</td>
</tr>
</tbody>
</table>

#### format_time(+Out, +Format, +StampOrDateTime)

Modelled after POSIX strftime(), using GNU extensions. *Out* is a destination as specified with with_output_to/2. *Format* is an atom or string with the following conversions. Conversions start with a tilde (%) character.\(^{48}\)

- a The abbreviated weekday name according to the current locale. Use format_time/4 for POSIX locale.
- A The full weekday name according to the current locale. Use format_time/4 for POSIX locale.
- b The abbreviated month name according to the current locale. Use format_time/4 for POSIX locale.
- B The full month name according to the current locale. Use format_time/4 for POSIX locale.
- c The preferred date and time representation for the current locale.
- C The century number (year/100) as a 2-digit integer.
- d The day of the month as a decimal number (range 01 to 31).
- D Equivalent to %m/%d/%y. \(\text{Yecch for Americans only. Americans should note that in other countries }%d/%m/%y\text{ is rather common. This means that in international context this format is ambiguous and should not be used.}\)
- e Like %d, the day of the month as a decimal number, but a leading zero is replaced by a space.
- E Modifier. Not implemented.
- F Equivalent to %Y-%m-%d (the ISO 8601 date format).
- g Like %G, but without century, i.e., with a 2-digit year (00-99).
- G The ISO 8601 year with century as a decimal number. The 4-digit year corresponding to the ISO week number (see %V). This has the same format and value as %y, except that if the ISO week number belongs to the previous or next year, that year is used instead.
- V The ISO 8601:1988 week number of the current year as a decimal number, range 01 to 53, where week 1 is the first week that has at least 4 days in the current year, and with Monday as the first day of the week. See also %U and %W.

\(^{48}\)Descriptions taken from Linux Programmer’s Manual
h Equivalent to %b.
H The hour as a decimal number using a 24-hour clock (range 00 to 23).
I The hour as a decimal number using a 12-hour clock (range 01 to 12).
j The day of the year as a decimal number (range 001 to 366).
k The hour (24-hour clock) as a decimal number (range 0 to 23); single digits are preceded by a blank. (See also %H.)
l The hour (12-hour clock) as a decimal number (range 1 to 12); single digits are preceded by a blank. (See also %I.)
m The month as a decimal number (range 01 to 12).
M The minute as a decimal number (range 00 to 59).
n A newline character.
O Modifier. Not implemented.
p Either ‘AM’ or ‘PM’ according to the given time value, or the corresponding strings for the current locale. Noon is treated as ‘pm’ and midnight as ‘am’.
P Like %p but in lowercase: ‘am’ or ‘pm’ or a corresponding string for the current locale.
r The time in a.m. or p.m. notation. In the POSIX locale this is equivalent to ‘%I:%M:%S %p’.
R The time in 24-hour notation (%H:%M). For a version including the seconds, see %T below.
s The number of seconds since the Epoch, i.e., since 1970-01-01 00:00:00 UTC.
S The second as a decimal number (range 00 to 60). (The range is up to 60 to allow for occasional leap seconds.)
t A tab character.
T The time in 24-hour notation (%H:%M:%S).
u The day of the week as a decimal, range 1 to 7, Monday being 1. See also %w.
U The week number of the current year as a decimal number, range 00 to 53, starting with the first Sunday as the first day of week 01. See also %V and %W.
w The day of the week as a decimal, range 0 to 6, Sunday being 0. See also %u.
W The week number of the current year as a decimal number, range 00 to 53, starting with the first Monday as the first day of week 01.
x The preferred date representation for the current locale without the time.
X The preferred time representation for the current locale without the date.
y The year as a decimal number without a century (range 00 to 99).
Y The year as a decimal number including the century.
z The time-zone as hour offset from GMT. Required to emit RFC822-conformant dates (using “%a, %d %b %Y %H:%M:%S %z”).
Z The time zone or name or abbreviation.
+ The date and time in date(1) format.
% A literal ‘%’ character.
format_time(+Out, +Format, +StampOrDateTime, +Locale)
Format time given a specified Locale. This predicate is a work-around for lacking proper portable and thread-safe time and locale handling in current C libraries. In its current implementation the only value allowed for Locale is posix, which currently only modifies the behaviour or the a, A, b and B format specifiers. The predicate is used to be able to emit POSIX locale week and month names for emitting standardised time-stamps such as RFC1123.

parse_time(+Text, -Stamp)
Parse a textual time representation, producing a time-stamp. Supported formats for Text are:

<table>
<thead>
<tr>
<th>Name</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>RFC 1123</td>
<td>Fri, 08 Dec 2006 15:29:44 GMT</td>
</tr>
</tbody>
</table>

4.34.2 Controlling the PLWIN.EXE console window

The Windows executable PLWIN.EXE console has a number of predicates to control the appearance of the console. Being totally non-portable, we do not advice using it for your own application, but use XPCE or another portable GUI platform instead. We give the predicates for reference here.

window_title(-Old, +New)
Unify Old with the title displayed in the console and change the title to New.\(^\text{49}\)

win_window_pos(+ListofOptions)
Interface to the MS-Windows SetWindowPos() function, controlling size, position and stacking order of the window. ListofOptions is a list that may hold any number of the terms below.

size(W, H)
Change the size of the window. W and H are expressed in character-units.

position(X, Y)
Change the top-left corner of the window. The values are expressed in pixel units.

zorder(ZOrder)
Change the location in the window stacking order. Values are bottom, top, topmost and notopmost. Topmost windows are displayed above all other windows.

show(Bool)
If true, show the window, if false hide the window.

activate
If present, activate the window.

win_has_menu
True if win_insert_menu/2 and win_insert_menu_item/4 are present.

win_insert_menu(+Label, +Before)
Insert a new entry (pulldown) in the menu. If the menu already contains this entry, nothing is done. The Label is the label and using the Windows conventions, a letter prefixed with & is underlined and defines the associated accelerator key. Before is the label before which this one must be inserted. Using – adds the new entry at the end (right). For example, the call below adds a Application entry just before the Help menu.

\(^{49}\)BUG: This predicate should have been called win_window_title for consistent naming.
4.35 FILE SYSTEM INTERACTION

\[
\text{win\_insert\_menu}('\&Application', '\&Help')
\]

\[
\text{win\_insert\_menu\_item}(+\text{Pulldown}, +\text{Label}, +\text{Before}, :\text{Goal})
\]

Add an item to the named \text{Pulldown} menu. \text{Label} and \text{Before} are handled as in \text{win\_insert\_menu/2}, but the label – inserts a separator. \text{Goal} is called if the user selects the item.

4.35 File System Interaction

\[
\text{access\_file}(+\text{File}, +\text{Mode})
\]

True if \text{File} exists and can be accessed by this prolog process under mode \text{Mode}. \text{Mode} is one of the atoms \text{read}, \text{write}, \text{append}, \text{exist}, \text{none} or \text{execute}. \text{File} may also be the name of a directory. Fails silently otherwise. \text{access\_file(File, none)} simply succeeds without testing anything.

If ‘Mode’ is \text{write} or \text{append}, this predicate also succeeds if the file does not exist and the user has write-access to the directory of the specified location.

\[
\text{exists\_file}(+\text{File})
\]

True if \text{File} exists and is a regular file. This does not imply the user has read and/or write permission for the file.

\[
\text{file\_directory\_name}(+\text{File}, -\text{Directory})
\]

Extracts the directory-part of \text{File}. The returned \text{Directory} name does not end in \text{/}. There are two special cases. The directory-name of \text{/} is \text{/} itself and the directory-name if \text{File} does not contain any \text{/} characters is ..

\[
\text{file\_base\_name}(+\text{File}, -\text{BaseName})
\]

Extracts the filename part from a path specification. If \text{File} does not contain any directory separators, \text{File} is returned.

\[
\text{same\_file}(+\text{File1}, +\text{File2})
\]

True if both filenames refer to the same physical file. That is, if \text{File1} and \text{File2} are the same string or both names exist and point to the same file (due to hard or symbolic links and/or relative vs. absolute paths).

\[
\text{exists\_directory} (+\text{Directory})
\]

True if \text{Directory} exists and is a directory. This does not imply the user has read, search and or write permission for the directory.

\[
\text{delete\_file} (+\text{File})
\]

Remove \text{File} from the file system.

\[
\text{rename\_file} (+\text{File1}, +\text{File2})
\]

Rename \text{File1} into \text{File2}. Currently files cannot be moved across devices.

\[
\text{size\_file} (+\text{File}, -\text{Size})
\]

Unify \text{Size} with the size of \text{File} in characters.
time_file(+File, -Time)
   Unify the last modification time of File with Time. Time is a floating point number expressing the seconds elapsed since Jan 1, 1970. See also convert_time/[2,8] and get_time/1.

absolute_file_name(+File, -Absolute)
   Expand a local file-name into an absolute path. The absolute path is canonised: references to . and .. are deleted. This predicate ensures that expanding a file-name it returns the same absolute path regardless of how the file is addressed. SWI-Prolog uses absolute file names to register source files independent of the current working directory. See also absolute_file_name/3. See also absolute_file_name/3 and expand_file_name/2.

absolute_file_name(+Spec, +Options, -Absolute)
   Converts the given file specification into an absolute path. Option is a list of options to guide the conversion:

   extensions(ListOfExtensions)
      List of file-extensions to try. Default is ''. For each extension, absolute_file_name/3 will first add the extension and then verify the conditions imposed by the other options. If the condition fails, the next extension of the list is tried. Extensions may be specified both as ..ext or plain ext.

   relative_to(+FileOrDir)
      Resolve the path relative to the given directory or directory the holding the given file. Without this option, paths are resolved relative to the working directory (see working_directory/2) or, if Spec is atomic and absolute_file_name/[2,3] is executed in a directive, it uses the current source-file as reference.

   access(Mode)
      Imposes the condition access_file(File, Mode). Mode is on of read, write, append, exist or none. See also access_file/2.

   file_type(Type)
      Defines extensions. Current mapping: txt implies [''], prolog implies ['.pl', ''], executable implies ['.so', ''], qlf implies ['.qlf', ''] and directory implies ['']. The file-type source is an alias for prolog for compatibility to SICStus Prolog. See also prolog_file_type/2.

   file_errors(fail/error)
      If error (default), throw and existence_error exception if the file cannot be found. If fail, stay silent.50

   solutions(first/all)
      If first (default), the predicates leaves no choice-point. Otherwise a choice-point will be left and backtracking may yield more solutions.

   expand(true/false)
      If true (default is false) and Spec is atomic, call expand_file_name/2 followed by member/2 on Spec before proceeding. This is a SWI-Prolog extension.

50 Silent operation was the default up to version 3.2.6.
The Prolog flag `verbose_file_search` can be set to `true` to help debugging Prolog’s search for files.

Compatibility considerations to common argument-order in ISO as well as SICStus `absolute_file_name/3` forced us to be flexible here. If the last argument is a list and the 2nd not, the arguments are swapped, making the call `absolute_file_name(+Spec, -Path, +Options)` valid as well.

### `is_absolute_file_name(+File)`

True if `File` specifies and absolute path-name. On Unix systems, this implies the path starts with a ‘/’. For Microsoft based systems this implies the path starts with ⟨letter⟩: This predicate is intended to provide platform-independent checking for absolute paths. See also `absolute_file_name/2` and `prolog_to_os_filename/2`.

### `file_name_extension(?Base, ?Extension, ?Name)`

This predicate is used to add, remove or test filename extensions. The main reason for its introduction is to deal with different filename properties in a portable manner. If the file system is case-insensitive, testing for an extension will be done case-insensitive too. `Extension` may be specified with or without a leading dot (.). If an `Extension` is generated, it will not have a leading dot.

### `expand_file_name(+WildCard, -List)`

Unify `List` with a sorted list of files or directories matching `WildCard`. The normal Unix wildcard constructs ‘?’, ‘*’, ‘[...]’ and ‘{...}’ are recognised. The interpretation of ‘{...}’ is interpreted slightly different from the C shell (csh(1)). The comma separated argument can be arbitrary patterns, including ‘{...}’ patterns. The empty pattern is legal as well: ‘\{.pl, \}’ matches either ‘.pl’ or the empty string.

If the pattern does contains wildcard characters, only existing files and directories are returned. Expanding a ‘pattern’ without wildcard characters returns the argument, regardless on whether or not it exists.

Before expanding wildcards, the construct `$var` is expanded to the value of the environment variable `var` and a possible leading ~ character is expanded to the user’s home directory.\(^{51}\)

### `prolog_to_os_filename(?PrologPath, ?OsPath)`

Converts between the internal Prolog pathname conventions and the operating-system pathname conventions. The internal conventions are Unix and this predicates is equivalent to `=/2` (unify) on Unix systems. On DOS systems it will change the directory-separator, limit the filename length map dots, except for the last one, onto underscores.

### `read_link(+File, -Link, -Target)`

If `File` points to a symbolic link, unify `Link` with the value of the link and `Target` to the file the link is pointing to. `Target` points to a file, directory or non-existing entry in the file system, but never to a link. Fails if `File` is not a link. Fails always on systems that do not support symbolic links.

---

\(^{51}\)On Windows, the home directory is determined as follows: if the environment variable `HOME` exists, this is used. If the variables `HOMEDRIVE` and `HOMEPATH` exist (Windows-NT), these are used. At initialisation, the system will set the environment variable `HOME` to point to the SWI-Prolog home directory if neither `HOME` nor `HOMEPATH` and `HOMEDRIVE` are defined.
tmp_file(+Base, -TmpName)
Create a name for a temporary file. Base is an identifier for the category of file. The TmpName is guaranteed to be unique. If the system halts, it will automatically remove all created temporary files.

make_directory(+Directory)
Create a new directory (folder) on the filesystem. Raises an exception on failure. On Unix systems, the directory is created with default permissions (defined by the process umask setting).

delete_directory(+Directory)
Delete directory (folder) from the filesystem. Raises an exception on failure. Please note that in general it will not be possible to delete a non-empty directory.

working_directory(-Old, +New)
Unify Old with an absolute path to the current working directory and change working directory to New. Use the pattern working_directory(CWD, CWD) to get the current directory. See also absolute_file_name/2 and chdir/1.\footnote{BUG: Some of the file-I/O predicates use local filenames. Changing directory while file-bound streams are open causes wrong results on telling/1, seeing/1 and current_stream/3}
Note that the working directory is shared between all threads.

chdir(+Path)
Compatibility predicate. New code should use working_directory/2.

### 4.36 User Top-level Manipulation

**break**
Recursively start a new Prolog top level. This Prolog top level has its own stacks, but shares the heap with all break environments and the top level. Debugging is switched off on entering a break and restored on leaving one. The break environment is terminated by typing the system’s end-of-file character (control-D). If the −t toplevel command line option is given this goal is started instead of entering the default interactive top level (prolog/0).

**abort**
Abort the Prolog execution and restart the top level. If the −t toplevel command line options is given this goal is started instead of entering the default interactive top level.

There are two implementations of abort/0. The default one uses the exception mechanism (see throw/1), throwing the exception $aborted. The other one uses the C-construct longjmp() to discard the entire environment and rebuild a new one. Using exceptions allows for proper recovery of predicates exploiting exceptions. Rebuilding the environment is safer if the Prolog stacks are corrupt. Therefore the system will use the rebuild-strategy if the abort was generated by an internal consistency check and the exception mechanism otherwise. Prolog can be forced to use the rebuild-strategy setting the Prolog flag abort_with_exception to false.

**halt**\footnote{[ISO]}
Terminate Prolog execution. Open files are closed and if the command line option −tty is not
4.37. CREATING A PROTOCOL OF THE USER INTERACTION

active the terminal status (see Unix stty(1)) is restored. Hooks may be registered both in Prolog and in foreign code. Prolog hooks are registered using \texttt{at.halt/1}. \texttt{halt/0} is equivalent to \texttt{halt(0)}.

\texttt{halt(+Status)} \quad ~\textbf{[ISO]}\quad \texttt{halt(0)}

Terminate Prolog execution with given status. Status is an integer. See also \texttt{halt/0}.

\texttt{prolog}

This goal starts the default interactive top level. Queries are read from the stream \texttt{user.input}. See also the Prolog flag \texttt{history}. The \texttt{prolog/0} predicate is terminated (succeeds) by typing the end-of-file character (typically control-D).

The following two hooks allow for expanding queries and handling the result of a query. These hooks are used by the top-level variable expansion mechanism described in section 2.8.

\texttt{expand\_query(+Query, -Expanded, +Bindings, -ExpandedBindings)}

Hook in module \texttt{user}, normally not defined. \texttt{Query} and \texttt{Bindings} represents the query read from the user and the names of the free variables as obtained using \texttt{read_term/3}. If this predicate succeeds, it should bind \texttt{Expanded} and \texttt{ExpandedBindings} to the query and bindings to be executed by the top-level. This predicate is used by the top-level (\texttt{prolog/0}). See also \texttt{expand\_answer/2} and \texttt{term\_expansion/2}.

\texttt{expand\_answer(+Bindings, -ExpandedBindings)}

Hook in module \texttt{user}, normally not defined. Expand the result of a successfully executed top-level query. \texttt{Bindings} is the query \texttt{⟨Name⟩ = ⟨Value⟩} binding list from the query. \texttt{ExpandedBindings} must be unified with the bindings the top-level should print.

4.37 Creating a Protocol of the User Interaction

SWI-Prolog offers the possibility to log the interaction with the user on a file. All Prolog interaction, including warnings and tracer output, are written on the protocol file.

\texttt{protocol(+File)}

Start protocolling on file \texttt{File}. If there is already a protocol file open then close it first. If \texttt{File} exists it is truncated.

\texttt{protocola(+File)}

Equivalent to \texttt{protocol/1}, but does not truncate the \texttt{File} if it exists.

\texttt{noprotocol}

Stop making a protocol of the user interaction. Pending output is flushed on the file.

\texttt{protocolling(-File)}

True if a protocol was started with \texttt{protocol/1} or \texttt{protocola/1} and unifies \texttt{File} with the current protocol output file.

\texttt{halt/0} does not work when not called from the \texttt{main} thread. In the current system a \texttt{permission\_error} exception is raised. Future versions may enable \texttt{halt/0} from any thread.

\texttt{A similar facility was added to Edinburgh C-Prolog by Wouter Jansweijer.}
4.38 Debugging and Tracing Programs

This section is a reference to the debugger interaction predicates. A more use-oriented overview of the debugger is in section 2.9.

If you have installed XPCE, you can use the graphical front-end of the tracer. This front-end is installed using the predicate `guitracer/0`.

### trace
Start the tracer. `trace/0` itself cannot be seen in the tracer. Note that the Prolog top-level treats `trace/0` special; it means ‘trace the next goal’.

### tracing
True if the tracer is currently switched on. `tracing/0` itself cannot be seen in the tracer.

### notrace
Stop the tracer. `notrace/0` itself cannot be seen in the tracer.

### guitracer
Installs hooks (see `prolog_trace_interception/4`) into the system that redirects tracing information to a GUI front-end providing structured access to variable-bindings, graphical overview of the stack and highlighting of relevant source-code.

### noguitracer
Reverts back to the textual tracer.

### trace(+Pred)
Equivalent to `trace(Pred, +all)`.

### trace(+Pred, +Ports)
Put a trace-point on all predicates satisfying the predicate specification `Pred`. `Ports` is a list of port names (`call`, `redo`, `exit`, `fail`). The atom `all` refers to all ports. If the port is preceded by a `−` sign the trace-point is cleared for the port. If it is preceded by a `+` the trace-point is set.

The predicate `trace/2` activates debug mode (see `debug/0`). Each time a port (of the 4-port model) is passed that has a trace-point set the goal is printed as with `trace/0`. Unlike `trace/0` however, the execution is continued without asking for further information. Examples:

```prolog
?- trace(hello).
Trace all ports of hello with any arity in any module.
?- trace(foo/2, +fail).
Trace failures of foo/2 in any module.
?- trace(bar/1, -all).
Stop tracing bar/1.
```

The predicate `debugging/0` shows all currently defined trace-points.

### notrace(+Goal)
Call `Goal`, but suspend the debugger while `Goal` is executing. The current implementation cuts the choice-points of `Goal` after successful completion. See `once/1`. Later implementations may have the same semantics as `call/1`. 
4.38. DEBUGGING AND TRACING PROGRAMS

debug
Start debugger. In debug mode, Prolog stops at spy- and trace-points, disables last-call optimisation and aggressive destruction of choice points to make debugging information accessible. Implemented by the Prolog flag debug.

nodebug
Stop debugger. Implemented by the Prolog flag debug. See also debug/0.

debugging
Print debug status and spy points on current output stream. See also the Prolog flag debug.

spy(+Pred)
Put a spy point on all predicates meeting the predicate specification Pred. See section 4.4.

nospy(+Pred)
Remove spy point from all predicates meeting the predicate specification Pred.

nospyall
Remove all spy points from the entire program.

leash(?Ports)
Set/query leashing (ports which allow for user interaction). Ports is one of +Name, -Name, ?Name or a list of these. +Name enables leashing on that port, -Name disables it and ?Name succeeds or fails according to the current setting. Recognised ports are: call, redo, exit, fail and unify. The special shorthand all refers to all ports, full refers to all ports except for the unify port (default). half refers to the call, redo and fail port.

visible(+Ports)
Set the ports shown by the debugger. See leash/1 for a description of the port specification. Default is full.

unknown(-Old, +New)
Edinburgh-prolog compatibility predicate, interfacing to the ISO prolog flag unknown. Values are trace (meaning error) and fail. If the unknown flag is set to warning, unknown/2 reports the value as trace.

style_check(+Spec)
Set style checking options. Spec is either +⟨option⟩, -⟨option⟩, ?.⟨⟨option⟩⟩\textsuperscript{55} or a list of such options. +⟨option⟩ sets a style checking option, -⟨option⟩ clears it and ?.⟨⟨option⟩⟩ succeeds or fails according to the current setting. consult/1 and derivatives resets the style checking options to their value before loading the file. If—for example—a file containing long atoms should be loaded the user can start the file with:

```prolog
:- style_check(-atom).
```

Currently available options are:

\textsuperscript{55}In older versions ‘?’ was a prefix operator. Inversions after 5.5.13, explicit brackets are needed.
### 4.39 Obtaining Runtime Statistics

**statistics(+Key, -Value)**

Unify system statistics determined by `Key` with `Value`. The possible keys are given in the table 4.2. The last part of the table contains keys for compatibility to other Prolog implementations (Quintus) for improved portability. Note that the ISO standard does not define methods to collect system statistics. Space unit is bytes\(^{56}\). Times are in seconds, represented as a floating point number. The Quintus compatibility keys express times in milliseconds.

**statistics**

Display a table of system statistics on the current output stream.

**time(+Goal)**

Execute `Goal` just like `once/1` (i.e., leaving no choice points), but print used time, number of logical inferences and the average number of `lips` (logical inferences per second). Note that SWI-Prolog counts the actual executed number of inferences rather than the number of passes through the call- and redo ports of the theoretical 4-port model.

### 4.40 Execution profiling

This section describes the hierarchical execution profiler introduced in SWI-Prolog 5.1.10. This profiler is based on ideas from `gprof` described in [Graham et al., 1982]. The profiler consists of two parts: the information-gathering is built into the kernel,\(^{57}\) and a presentation component which is defined in the `statistics` library. The latter can be hooked, which is used by the XPCE module `swi/pce_profile` to provide an interactive graphical representation of results.

---

\(^{56}\)This may change to ‘cells’ to enhance compatibility between the 32- and 64-bit versions.

\(^{57}\)There are two implementations; one based on `setitimer()` using the `SIGPROF` signal and one using Windows Multi Media (MM) timers. On other systems the profiler is not provided.

Table 4.2: Keys for statistics/2
4.40.1 Profiling predicates

Currently, the interface is kept compatible with the old profiler. As experience grows, it is likely that the old interface is replaced with one that better reflects the new capabilities. Feel free to examine the internal interfaces and report useful application thereof.

\texttt{profile(\textit{Goal})}

Execute \textit{Goal} just like \texttt{time/1}, collecting profiling statistics and call \texttt{show_profile(plain, Number)}. With XPCE installed this opens a graphical interface to the collected profiling data.

\texttt{profile(\textit{Goal}, \texttt{Style}, \texttt{Number})}

Execute \textit{Goal} just like \texttt{time/1}. Collect profiling statistics and show the top \texttt{Number} procedures on the current output stream (see \texttt{show_profile/1}) using \texttt{Style}. The results are kept in the database until \texttt{reset_profiler/0} or \texttt{profile/3} is called and can be displayed again with \texttt{show_profile/1}. The \texttt{profile/1} predicate is a backward compatibility interface to \texttt{profile/1}. The other predicates in this section are low-level predicates for special cases.

\texttt{show_profile(\texttt{Style}, \texttt{Number})}

Show the collected results of the profiler. It shows the top \texttt{Number} predicates according the percentage CPU-time used. If \texttt{Style} is \texttt{plain} the time spent in the predicates itself is displayed. If \texttt{Style} is \texttt{cumulative} the time spent in its siblings (callees) is added to the predicate.

This predicate first calls \texttt{prolog:show_profile_hook/2}. If XPCE is loaded this hook is used to activate a GUI interface to visualise the profile results.

\texttt{show_profile(+Number)}

Compatibility. Same as \texttt{show_profile(plain, Number)}.

\texttt{profiler(-Old, +New)}

Query or change the status of the profiler. The status is a boolean (\texttt{true} or \texttt{false}) stating whether or not the profiler is collecting data. It can be used to enable or disable profiling certain parts of the program.

\texttt{reset_profiler}

Switches the profiler to \texttt{false} and clears all collected statistics.

\texttt{noprofile(+Name/+Arity, \ldots)}

Declares the predicate \texttt{Name/Arity} to be invisible to the profiler. The time spend in the named predicate is added to the caller and the callees are linked directly to the caller. This is particularly useful for simple meta-predicates such as \texttt{call/1}, \texttt{ignore/1}, \texttt{catch/3}, etc.

4.40.2 Visualizing profiling data

Browsing the annotated call-tree as described in section 4.40.3 itself is not very attractive. Therefore, the results are combined per predicate, collecting all \textit{callers} and and \textit{callees} as well as the propagation of time and activations in both directions. Figure 4.1 illustrates this. The central yellowish line is the ‘current’ predicate with counts for time spent in the predicate (‘Self’), time spent in its children (‘Siblings’), activations through the call and redo ports. Above that are the \textit{callers}. Here, the two time fields indicate how much time is spent serving each of the callers. The columns sum to the time in the yellowish line. The caller <\texttt{recursive}> are the number of recursive calls. Below the yellowish lines
are the callees, with the time spent in the callee itself for serving the current predicate and the time spent in the callees of the callee (‘siblings’), so the whole time-block adds up to the ‘siblings’ field of the current predicate. The ‘access’ fields show how many times the current predicate accesses each of the callees.

The predicates have a menu that allows changing the view of the detail window to the given caller or callee, showing the documentation (if it is a built-in) and/or jumping to the source.

The statistics shown in the report-field of figure 4.1 show the following information:

- **samples**
  Number of times the call-tree was sampled for collecting time statistics. On most hardware the resolution of SIGPROF is 1/100 second. This number must be sufficiently large to get reliable timing figures. The Time menu allows viewing time as samples, relative time or absolute time.

- **sec**
  Total user CPU time with the profiler active.

- **predicates**
  Total count of predicates that have been called at least one time during the profile.

- **nodes**
  Number of nodes in the call-tree.

- **distortion**
  How much of the time is spend building the call-tree as a percentage of the total execution time. Timing samples while the profiler is building the call-tree are not added to the call-tree.

### 4.40.3 Information gathering

While the program executes under the profiler, the system builds a *dynamic* call-tree. It does this using three hooks from the kernel: one that starts a new goal (profCall), one that tells the system which goal is resumed after an *exit* (profExit) and one that tells the system which goal is resumed after a *fail* (i.e. which goal is used to retry (profRedo)). The profCall() function finds or creates the subnode for the argument predicate below the current node, increments the call-count of this link and returns the sub-node which is recorded in the Prolog stack-frame. Choice-points are marked with the current profiling node. profExit() and profRedo() pass the profiling node where execution resumes.
Just using the above algorithm would create a much too big tree due to recursion. For this reason the system performs detection of recursion. In the simplest case, recursive procedures increment the ‘recursive’ count on the current node. Mutual recursion however is not easily detected. For example, call/1 can call a predicate that uses call/1 itself. This can be viewed as a recursive invocation, but this is generally not desirable. Recursion is currently assumed if the same predicate with the same parent appears higher in the call-graph. Early experience with some arbitrary non-trivial programs are promising.

The last part of the profiler collects statistics on the CPU-time used in each node. On systems providing setitimer() with SIGPROF, it ‘ticks’ the current node of the call-tree each time the timer fires. On Windows a MM-timer in a separate thread checks 100 times per second how much time is spent in the profiled thread and adds this to the current node. See section 4.40.3 for details.

**Profiling in the Windows Implementation**

Profiling in the Windows version is similar but as profiling is a statistical process it is good to be aware of the implementation\(^\text{58}\) for proper interpretation of the results.

Windows does not provide timers that fire asynchronously, frequent and proportional to the CPU time used by the process. Windows does provide multi-media timers that can run at high frequency. Such timers however run in a separate thread of execution and they are fired on the wall-clock rather than the amount of CPU time used. The profiler installs such a timer running, for saving CPU time, rather inaccurately at about 100 Hz. Each time it is fired, it determines the milliseconds CPU time used by Prolog since the last time it was fired. If this value is non-zero, active predicates are incremented with this value.

### 4.41 Memory Management

**garbage_collect**

Invoke the global- and trail stack garbage collector. Normally the garbage collector is invoked automatically if necessary. Explicit invocation might be useful to reduce the need for garbage collections in time critical segments of the code. After the garbage collection trim_stacks/0 is invoked to release the collected memory resources.

**garbage_collect_atoms**

Reclaim unused atoms. Normally invoked after agc_margin (a Prolog flag) atoms have been created. On multi-threaded versions the actual collection is delayed until there are no threads performing normal garbage collection. In this case garbage_collect_atoms/0 returns immediately. Note this implies there is no guarantee it will ever happen as there may always be threads performing garbage collection.

**trim_stacks**

Release stack memory resources that are not in use at this moment, returning them to the operating system. Trim stack is a relatively cheap call. It can be used to release memory resources in a backtracking loop, where the iterations require typically seconds of execution time and very different, potentially large, amounts of stack space. Such a loop should be written as follows:

\(^{58}\)We hereby acknowledge Lionel Fourquaux, who suggested the design described here after a newsnet enquiry.
4.42. WINDOWS DDE INTERFACE

The prolog top level loop is written this way, reclaiming memory resources after every user query.

**stack\_parameter(+Stack, +Key, -Old, +New)**

Query/set a parameter for the runtime stacks. *Stack* is one of local, global, trail or argument. The table below describes the *Key/Value* pairs. Old is first unified with the current value.

<table>
<thead>
<tr>
<th>limit</th>
<th>Maximum size of the stack in bytes</th>
</tr>
</thead>
<tbody>
<tr>
<td>min_free</td>
<td>Minimum free space at entry of foreign predicate</td>
</tr>
</tbody>
</table>

This predicate is currently only available on versions that use the stack-shifter to enlarge the runtime stacks when necessary. It’s definition is subject to change.

4.42 Windows DDE interface

The predicates in this section deal with MS-Windows ‘Dynamic Data Exchange’ or DDE protocol. A Windows DDE conversation is a form of interprocess communication based on sending reserved window-events between the communicating processes.

See also section 9.4 for loading Windows DLL’s into SWI-Prolog.

4.42.1 DDE client interface

The DDE client interface allows Prolog to talk to DDE server programs. We will demonstrate the use of the DDE interface using the Windows PROGMAN (Program Manager) application:

```
1 ?- open_dde_conversation(progman, progman, C).
C = 0
2 ?- dde_request(0, groups, X)
--> Unifies X with description of groups
3 ?- dde_execute(0, '[CreateGroup("DDE Demo")]').
Yes
4 ?- close_dde_conversation(0).
Yes
```

---

59This interface is contributed by Don Dwiggins.
For details on interacting with progman, use the SDK online manual section on the Shell DDE interface. See also the Prolog library(progman), which may be used to write simple Windows setup scripts in Prolog.

**open_dde_conversation(+Service, +Topic, -Handle)**

Open a conversation with a server supporting the given service name and topic (atoms). If successful, Handle may be used to send transactions to the server. If no willing server is found this predicate fails silently.

**close_dde_conversation(+Handle)**

Close the conversation associated with Handle. All opened conversations should be closed when they’re no longer needed, although the system will close any that remain open on process termination.

**dde_request(+Handle, +Item, -Value)**

Request a value from the server. Item is an atom that identifies the requested data, and Value will be a string (CF_TEXT data in DDE parlance) representing that data, if the request is successful. If unsuccessful, Value will be unified with a term of form error(⟨Reason⟩), identifying the problem. This call uses SWI-Prolog string objects to return the value rather then atoms to reduce the load on the atom-space. See section 4.23 for a discussion on this data type.

**dde_execute(+Handle, +Command)**

Request the DDE server to execute the given command-string. Succeeds if the command could be executed and fails with error message otherwise.

**ddepoke(+Handle, +Item, +Command)**

Issue a POKE command to the server on the specified Item. Command is passed as data of type CF_TEXT.

### 4.42.2 DDE server mode

The (autoload) library(dde) defines primitives to realise simple DDE server applications in SWI-Prolog. These features are provided as of version 2.0.6 and should be regarded prototypes. The C-part of the DDE server can handle some more primitives, so if you need features not provided by this interface, please study library(dde).

**dde_register_service(+Template, +Goal)**

Register a server to handle DDE request or DDE execute requests from other applications. To register a service for a DDE request, Template is of the form:

```
+Service(+Topic, +Item, +Value)
```

Service is the name of the DDE service provided (like progman in the client example above). Topic is either an atom, indicating Goal only handles requests on this topic or a variable that also appears in Goal. Item and Value are variables that also appear in Goal. Item represents the request data as a Prolog atom.\(^{50}\)

---

\(^{50}\)Up-to version 3.4.5 this was a list of character codes. As recent versions have atom garbage collection there is no need for this anymore.
The example below registers the Prolog `current_prolog_flag/2` predicate to be accessible from other applications. The request may be given from the same Prolog as well as from another application.

```
?- dde_register_service(prolog(current_prolog_flag, F, V),
   current_prolog_flag(F, V)).

?- open_dde_conversation(prolog, current_prolog_flag, Handle),
   dde_request(Handle, home, Home),
   close_dde_conversation(Handle).
```

Home = '/usr/local/lib/pl-2.0.6/'

Handling DDE `execute` requests is very similar. In this case the template is of the form:

```
+Service(+Topic, +Item)
```

Passing a `Value` argument is not needed as execute requests either succeed or fail. If `Goal` fails, a ‘not processed’ is passed back to the caller of the DDE request.

```
dde_unregister_service(+Service)
```

Stop responding to `Service`. If Prolog is halted, it will automatically call this on all open services.

```
dde_current_service(-Service, -Topic)
```

Find currently registered services and the topics served on them.

```
dde_current_connection(-Service, -Topic)
```

Find currently open conversations.

### 4.43 Miscellaneous

```
dwim_match(+Atom1, +Atom2)
```

True if `Atom1` matches `Atom2` in ‘Do What I Mean’ sense. Both `Atom1` and `Atom2` may also be integers or floats. The two atoms match if:

- They are identical
- They differ by one character (spy ≡ spu)
- One character is inserted/deleted (debug ≡ deug)
- Two characters are transposed (trace ≡ tarce)
- ‘Sub-words’ are glued differently (existsfile ≡ existsFile ≡ exists_file)
- Two adjacent sub words are transposed (existsFile ≡ fileExists)

```
dwim_match(+Atom1, +Atom2, -Difference)
```

Equivalent to `dwim_match/2`, but unifies `Difference` with an atom identifying the difference between `Atom1` and `Atom2`. The return values are (in the same order as above): `equal`, `mismatched_char`, `inserted_char`, `transposed_char`, `separated` and `transposed_word`. 
wildcard_match(+Pattern, +String)

True if String matches the wildcard pattern Pattern. Pattern is very similar the Unix csh pattern matcher. The patterns are given below:

? Matches one arbitrary character.
* Matches any number of arbitrary characters.
[...] Matches one of the characters specified between the brackets.
⟨char1⟩−⟨char2⟩ indicates a range.
{...} Matches any of the patterns of the comma separated list between the braces.

Example:

?- wildcard_match('*[a-z]*.pro,pl[%^]', 'a_hello.pl%').
Yes

sleep(+Time)

Suspend execution Time seconds. Time is either a floating point number or an integer. Granularity is dependent on the system’s timer granularity. A negative time causes the timer to return immediately. On most non-realtime operating systems we can only ensure execution is suspended for at least Time seconds.

On Unix systems the sleep/1 predicate is realised—in order of preference—by nanosleep(), usleep(), select() if the time is below 1 minute or sleep(). On Windows systems Sleep() is used.
5.1 Why Using Modules?

In traditional Prolog systems the predicate space was flat. This approach is not very suitable for the development of large applications, certainly not if these applications are developed by more than one programmer. In many cases, the definition of a Prolog predicate requires sub-predicates that are intended only to complete the definition of the main predicate. With a flat and global predicate space these support predicates will be visible from the entire program.

For this reason, it is desirable that each source module has its own predicate space. A module consists of a declaration for its name, its public predicates and the predicates themselves. This approach allows the programmer to use short (local) names for support predicates without worrying about name conflicts with the support predicates of other modules. The module declaration also makes explicit which predicates are meant for public usage and which for private purposes. Finally, using the module information, cross reference programs can indicate possible problems much better.

5.2 Name-based versus Predicate-based Modules

Two approaches to realize a module system are commonly used in Prolog and other languages. The first one is the name based module system. In these systems, each atom read is tagged (normally prefixed) with the module name, with the exception of those atoms that are defined public. In the second approach, each module actually implements its own predicate space.

A critical problem with using modules in Prolog is introduced by the meta-predicates that transform between Prolog data and Prolog predicates. Consider the case where we write:

```prolog
:- module(extend, [add_extension/3]).

add_extension(Extension, Plain, Extended) :-
    maplist(extend_atom(Extension), Plain, Extended).

extend_atom(Extension, Plain, Extended) :-
    atom_concat(Plain, Extension, Extended).
```

In this case we would like maplist to call extend_atom/3 in the module extend. A name based module system will do this correctly. It will tag the atom extend_atom with the module and maplist will use this to construct the tagged term extend_atom/3. A name based module however, will not only tag the atoms that will eventually be used to refer to a predicate, but all atoms that are not declared public. So, with a name based module system also data is local to the module. This introduces another serious problem:
This code uses a simple object-oriented implementation technique where atoms are used as method selectors. Using a name-based module system, this code will not work, unless we declare the selectors public atoms in all modules that use them. Predicate-based module systems do not require particular precautions for handling this case.

It appears we have to choose either to have local data, or to have trouble with meta-predicates. Probably it is best to choose for the predicate-based approach as novice users will not often write generic meta-predicates that have to be used across multiple modules, but are likely to write programs that pass data around across modules. Experienced Prolog programmers should be able to deal with the complexities of meta-predicates in a predicate-based module system.

5.3 Defining a Module

Modules normally are created by loading a module file. A module file is a file holding a module/2 directive as its first term. The module/2 directive declares the name and the public (i.e., externally visible) predicates of the module. The rest of the file is loaded into the module. Below is an example of a module file, defining reverse/2.

```prolog
:- module(reverse, [reverse/2]).

reverse(List1, List2) :-
    rev(List1, [], List2).

rev([], List, List).
rev([Head|List1], List2, List3) :-
    rev(List1, [Head|List2], List3).
```

5.4 Importing Predicates into a Module

As explained before, in the predicate-based approach adapted by SWI-Prolog, each module has its own predicate space. In SWI-Prolog, a module initially is completely empty. Predicates can be added to a module by loading a module file as demonstrated in the previous section, using assert or by importing them from another module.

Two mechanisms for importing predicates explicitly from another module exist. The use_module/[1,2] predicates load a module file and import (part of the) public predicates of the file. The import/1 predicate imports any predicate from any module.
use_module(+File)
Load the file(s) specified with File just like ensure_loaded/1. The files must all be module files. All exported predicates from the loaded files are imported into the context module. This predicate is equivalent to ensure_loaded/1, except that it raises an error if File is not a module file.

use_module(+File, +ImportList)
Load the file specified with File (only one file is accepted). File must be a module file. ImportList is a list of predicate indicators specifying the predicates that will be imported from the loaded module. If a predicate is specified that is not exported from the loaded module a warning will be printed. The predicate will nevertheless be imported to simplify debugging. ImportList also allows for renaming or import-everything-except. See also import option of load_files/2. The first example below loads member/2 from the lists library and append/2 under the name list_concat, which how this predicate is named in YAP. The second example loads a all exports from library option, except for meta_options/3. These renaming facilities are generally used to deal with portability issues with as few as possible changes to the actual code. See also section C and section 5.5.

:­ use_module(library(lists), [ member/2, append/2 as list_concat ]).
:­ use_module(library(option), except([meta_options/3])).

import(+PredicateIndicator)
Import predicate PredicateIndicator into the current context module. PredicateIndicator must specify the source module using the ⟨module⟩:⟨pi⟩ construct. Note that predicates are normally imported using one of the directives use_module/[1,2]. The import/1 alternative is meant for handling imports into dynamically created modules. See also export/1 and export_list/2.

It would be rather inconvenient to have to import each predicate referred to by the module, including the system predicates. For this reason each module is assigned a default module. All predicates in the default module are available without extra declarations. Their definition however can be overruled in the local module. This schedule is implemented by the exception handling mechanism of SWI-Prolog: if an undefined predicate exception is raised for a predicate in some module, the exception handler first tries to import the predicate from one of the module’s import modules. On success, normal execution is resumed.

5.4.1 Reserved Modules
SWI-Prolog contains two special modules. The first one is the module system. This module contains all built-in predicates described in this manual. Module system has no default module assigned to it. The second special module is the module user. This module forms the initial working space of the user. Initially it is empty. The import module of module user is system, making all built-in predicate definitions available as defaults. Built-in predicates thus can be overruled by defining them in module user before they are used.

All other modules import from the module user. This implies they can use all predicates imported into user without explicitly importing them.
5.5 Composing modules from other modules

The predicates in this section are intended to create new modules from the content of other modules. Below is an example to define a composite module. The example exports all public predicates of module_1, module_2 and module_3, pred/1 from module_4, all predicates from module_5 except do_not_use/1 and all predicates from module_6 while renaming pred/1 into mypred/1.

```prolog
:- module(my_composite, []).
:- reexport([ module_1,
               module_2,
               module_3
             ]).
:- reexport(module_4, [ pred/1 ]).
:- reexport(module_5, except([do_not_use/1])).
:- reexport(module_6, except([pred/1 as mypred])).
```

**reexport(+Files)**

Load and import predicates as use_modules/1 and re-export all imported predicates. The reexport declarations must immediately follow the module declaration.

**reexport(+File, +Import)**

Import from File as use_module/2 and re-export the imported predicates. The reexport declarations must immediately follow the module declaration.

5.6 Using the Module System

The current structure of the module system has been designed with some specific organisations for large programs in mind. Many large programs define a basic library layer on top of which the actual program itself is defined. The module user, acting as the default module for all other modules of the program can be used to distribute these definitions over all program module without introducing the need to import this common layer each time explicitly. It can also be used to redefine built-in predicates if this is required to maintain compatibility to some other Prolog implementation. Typically, the loadfile of a large application looks like this:

```prolog
:- use_module(compatibility). % load XYZ prolog compatibility

:- use_module(
               [ error
                 , goodies
                 , debug
                 , virtual_machine
                 , ...
               ]).

:- ensure_loaded(
                 [ ... ]).
```
The ‘use_module’ declarations will import the public predicates from the generic modules into the user module. The ‘ensure_loaded’ directive loads the modules that constitute the actual application. It is assumed these modules import predicates from each other using use_module/[1,2] as far as necessary.

In combination with the object-oriented schema described below it is possible to define a neat modular architecture. The generic code defines general utilities and the message passing predicates (invoke/3 in the example below). The application modules define classes that communicate using the message passing predicates.

### 5.6.1 Object Oriented Programming

Another typical way to use the module system is for defining classes within an object oriented paradigm. The class structure and the methods of a class can be defined in a module and the explicit module-boundary overruling describes in section 5.7.2 can by used by the message passing code to invoke the behaviour. An outline of this mechanism is given below.

```prolog
% Define class point
:- module(point, []). % class point, no exports
%
% name type, default access
% value
%  variable(x, integer, 0, both).
%  variable(y, integer, 0, both).
%
% method name predicate name arguments

behaviour(mirror, mirror, []).

mirror(P) :-
    fetch(P, x, X),
    fetch(P, y, Y),
    store(P, y, X),
    store(P, x, Y).
```

The predicates fetch/3 and store/3 are predicates that change instance variables of instances. The figure below indicates how message passing can easily be implemented:

```prolog
% invoke(+Instance, +Selector, ?ArgumentList)
% send a message to an instance

invoke(I, S, Args) :-
    class_of_instance(I, Class),
    Class:behaviour(S, P, ArgCheck), !,
    convert_arguments(ArgCheck, Args, ConvArgs),
    Goal =.. [P|ConvArgs],
    Class:Goal.
```

SWI-Prolog 5.6 Reference Manual
The construct \(\langle\text{Module}\rangle:\langle\text{Goal}\rangle\) explicitly calls \textit{Goal} in module \textit{Module}. It is discussed in more detail in section 5.7.

### 5.7 Meta-Predicates in Modules

As indicated in the introduction, the problem with a predicate based module system lies in the difficulty to find the correct predicate from a Prolog term. The predicate ‘solution(Solution)’ can exist in more than one module, but ‘assert(solution(4))’ in some module is supposed to refer to the correct version of solution/1.

Various approaches are possible to solve this problem. One is to add an extra argument to all predicates (e.g. ‘assert(Module, Term)’). Another is to tag the term somehow to indicate which module is desired (e.g. ‘assert(Module:Term)’). Both approaches are not very attractive as they make the user responsible for choosing the correct module, inviting unclear programming by asserting in other modules. The predicate \textit{assert/1} is supposed to assert in the module it is called from and should do so without being told explicitly. For this reason, the notion \textit{context module} has been introduced.

#### 5.7.1 Definition and Context Module

Each predicate of the program is assigned a module, called its \textit{definition module}. The definition module of a predicate is always the module in which the predicate was originally defined. Each active goal in the Prolog system has a \textit{context module} assigned to it.

The context module is used to find predicates from a Prolog term. By default, this module is the definition module of the predicate running the goal. For meta-predicates however, this is the context module of the goal that invoked them. We call this \textit{module\_transparent} in SWI-Prolog. In the ‘using maplist’ example above, the predicate \textit{maplist/3} is declared \textit{module\_transparent}. This implies the context module remains \textit{extend}, the context module of \textit{add\_extension/3}. This way \textit{maplist/3} can decide to call \textit{extend\_atom} in module \textit{extend\_extension} rather than in its own definition module.

All built-in predicates that refer to predicates via a Prolog term are declared \textit{module\_transparent}. Below is the code defining \textit{maplist}.

```prolog
:- module(maplist, maplist/3).
:- module_transparent maplist/3.

% maplist(+Goal, +List1, ?List2) % True if Goal can successfully be applied to all successive pairs of elements of List1 and List2.
maplist(_, [], []). 
maplist(Goal, [Elem1|Tail1], [Elem2|Tail2]) :-
apply(Goal, [Elem1, Elem2]),
maplist(Goal, Tail1, Tail2).
```

SWI-Prolog 5.6 Reference Manual
5.7.2 Overruling Module Boundaries

The mechanism above is sufficient to create an acceptable module system. There are however cases in which we would like to be able to overrule this schema and explicitly call a predicate in some module or assert explicitly in some module. The first is useful to invoke goals in some module from the user’s top-level or to implement a object-oriented system (see above). The latter is useful to create and modify dynamic modules (see section 5.8).

For this purpose, the reserved term :/2 has been introduced. All built-in predicates that transform a term into a predicate reference will check whether this term is of the form ‘(Module):(Term)’. If so, the predicate is searched for in Module instead of the goal’s context module. The : operator may be nested, in which case the inner-most module is used.

The special calling construct ⟨Module⟩:⟨Goal⟩ pretends Goal is called from Module instead of the context module. Examples:

?- assert(world:done). % asserts done/0 into module world
?- world:assert(done). % the same
?- world:done. % calls done/0 in module world

5.8 Dynamic Modules

So far, we discussed modules that were created by loading a module-file. These modules have been introduced on facilitate the development of large applications. The modules are fully defined at load-time of the application and normally will not change during execution. Having the notion of a set of predicates as a self-contained world can be attractive for other purposes as well. For example, assume an application that can reason about multiple worlds. It is attractive to store the data of a particular world in a module, so we extract information from a world simply by invoking goals in this world.

Dynamic modules can easily be created. Any built-in predicate that tries to locate a predicate in a specific module will create this module as a side-effect if it did not yet exist. Example:

?- assert(world_a:consistent),
   world_a:unknown(_, fail).

These calls create a module called ‘world_a’ and make the call ‘world_a:consistent’ succeed. Undefined predicates will not start the tracer or autoloader for this module (see unknown/2).

Import and export from dynamically created world is arranged via the predicates import/1 and export/1:

?- world_b:export(solve(_,_)). % exports solve/2 from world_b
?- world_c:import(world_b:solve(_,_)). % and import it to world_c

5.9 Module Handling Predicates

This section gives the predicate definitions for the remaining built-in predicates that handle modules.
:- module(+Module, +PublicList)
   This directive can only be used as the first term of a source file. It declares the file to be a
   module file, defining Module and exporting the predicates of PublicList. PublicList is a list of
   predicate indicators (name/arity or name//arity pairs) or operator declarations using the format
   op(Precedence, Type, Name). Operators defined in the export list are available inside the
   module as well as to modules importing this module. See also section 4.24.

module_transparent +Preds
   Preds is a comma separated list of name/arity pairs (like dynamic/1). Each goal associated
   with a transparent declared predicate will inherit the context module from its parent goal.

meta_predicate +Heads
   This predicate is defined in quintus and provides a partial emulation of the Quintus predicate.
   See section 5.10.1 for details.

current_module(-Module)
   Generates all currently known modules.

current_module(?Module, ?File)
   Is true if File is the file from which Module was loaded. File is the internal canonical filename.
   See also source_file/[1,2].

context_module(-Module)
   Unify Module with the context module of the current goal. context_module/1 itself is
   transparent.

strip_module(+Term, -Module, -Plain)
   Used in module transparent or meta-predicates to extract the referenced module and plain term.
   If Term is a module-qualified term, i.e. of the format Module:Plain, Module and Plain are
   unified to these values. Otherwise Plain is unified to Term and Module to the context module.

export(+PredicateIndicator, . . .)
   Add a predicate to the public list of the context module. This implies the predicate will be
   imported into another module if this module is imported with use_module/[1,2]. Note
   that predicates are normally exported using the directive module/2. export/1 is meant to
   handle export from dynamically created modules.

export_list(+Module, ?Exports)
   Unifies Exports with a list of predicate indicators, one for each public predicate of Module.
   The order of the terms in Exports is not defined. Predicate indicators are in canonical form (i.e.
   always using Name/Arity and never the DCG form Name//Arity). Future versions may also
   use the DCG form and include public operators. See also predicate_property/2.

import_module(+Module, -Import)
   True if Import is defined as an import module for Module. All normal modules only import
   from user, which imports from system. The predicates add_import_module/3 and
   delete_import_module/2 can be used to manipulate the import list.

add_import_module(+Module, +Import, +StartOrEnd)
   If Import is not already an import module for Module, add it to this list at the start or end
   depending on StartOrEnd. See also import_module/2 and delete_import_module/2.
5.10 Compatibility of the Module System

The principles behind the module system of SWI-Prolog differ in a number of aspects from the Quintus Prolog module system.

- The SWI-Prolog module system allows the user to redefine system predicates.
- All predicates that are available in the system and user modules are visible in all other modules as well.
- Quintus has the ‘meta_predicate/1’ declaration were SWI-Prolog has the module_transparent/1 declaration.
- Operator declarations are local to a module and may be exported.

The meta_predicate/1 declaration causes the compiler to tag arguments that pass module sensitive information with the module using the :/2 operator. This approach has some disadvantages:

- Changing a meta_predicate declaration implies all predicates calling the predicate need to be reloaded. This can cause serious consistency problems.
- It does not help for dynamically defined predicates calling module sensitive predicates.
- It slows down the compiler (at least in the SWI-Prolog architecture).
- At least within the SWI-Prolog architecture the run-time overhead is larger than the overhead introduced by the transparent mechanism.
:- module(findall, [findall/3]).

:- dynamic
    solution/1.

:- module_transparent
    findall/3,
    store/2.

findall(Var, Goal, Bag) :-
    assert(findall:solution('$mark')),
    store(Var, Goal),
    collect(Bag).

store(Var, Goal) :- % refers to context module of
    Goal, % caller of findall/3
    assert(findall:solution(Var)),
    fail.
store(_, _).

collect(Bag) :-
    ..., 

Figure 5.1: findall/3 using modules

Unfortunately the transparent predicate approach also has some disadvantages. If a predicate $A$ passes module sensitive information to a predicate $B$, passing the same information to a module sensitive system predicate both $A$ and $B$ should be declared transparent. Using the Quintus approach only $A$ needs to be treated special (i.e., declared with meta_predicate/1). A second problem arises if the body of a transparent predicate uses module sensitive predicates for which it wants to refer to its own module. Suppose we want to define findall/3 using assert/1 and retract/1. The example in figure 5.1 gives the solution.

5.10.1 Emulating meta_predicate

The Quintus meta_predicate/1 directive can in many cases be replaced by the transparent declaration. Below is the definition of meta_predicate/1 as available from quintus.

:- op(1150, fx, (meta_predicate)).

meta_predicate((Head, More)) :- !,
    meta_predicate1(Head),
    meta_predicate(More).

1 Although this would make it impossible to call $B$ directly.
2 The system version uses recordz/2 and recorded/3.
meta_predicate(Head) :-
    meta_predicate1(Head).

meta_predicate1(Head) :-
    Head =.. [Name|Arguments],
    member(Arg, Arguments),
    module_expansion_argument(Arg), !,
    functor(Head, Name, Arity),
    module_transparent(Name/Arity).
meta_predicate1(_). % just a mode declaration

module_expansion_argument(:).
module_expansion_argument(N) :- integer(N).

The discussion above about the problems with the transparent mechanism show the two cases in which this simple transformation does not work.
This chapter deals with extensions primarily designed to support constraint logic programming (CLP).

6.1 Attributed variables

Attributed variables provide a technique for extending the Prolog unification algorithm [Holzbaur, 1990] by hooking the binding of attributed variables. There is little consensus in the Prolog community on the exact definition and interface to attributed variables. The SWI-Prolog interface is identical to the one realised by Bart Demoen for hProlog [Demoen, 2002].

Binding an attributed variable schedules a goal to be executed at the first possible opportunity. In the current implementation the hooks are executed immediately after a successful unification of the clause-head or successful completion of a foreign language (built-in) predicate. Each attribute is associated to a module and the hook (attr_unify_hook/2) is executed in this module. The example below realises a very simple and incomplete finite domain reasoner.

```
:- module(domain, [ domain/2 % Var, ?Domain ]) .
:- use_module(library(ordsets)).

domain(X, Dom) :-
    var(Dom), !,  
    get_attr(X, domain, Dom).

domain(X, List) :-
    list_to_ord_set(List, Domain),
    put_attr(Y, domain, Domain),
    X = Y.

% An attributed variable with attribute value Domain has been
% assigned the value Y

attr_unify_hook(Domain, Y) :-
    ( get_attr(Y, domain, Dom2) 
      -> ord_intersection(Domain, Dom2, NewDomain),
         ( NewDomain == [] 
           -> fail 
           ; NewDomain = [Value] 
           -> Y = Value 
           ; put_attr(Y, domain, NewDomain) 
         ) 
    % Y = Value
```
6.1. ATTRIBUTED VARIABLES

\)
; var(Y)
-> put_attr(Y, domain, Domain)
; ord_memberchk(Y, Domain)
).

% Translate attributes from this module to residual goals

attribute_goals(X) -->
{ get_attr(X, domain, List) },
domain(X, List).

Before explaining the code we give some example queries:

?- domain(X, [a,b]), X = c
fail
?- domain(X, [a,b]), domain(X, [a,c]).
X = a
?- domain(X, [a,b,c]), domain(X, [a,c]).
domain(X, [a, c])

The predicate domain/2 fetches (first clause) or assigns (second clause) the variable a domain, a set of values it can be unified with. In the second clause first associates the domain with a fresh variable and then unifies X to this variable to deal with the possibility that X already has a domain. The predicate attr_unify_hook/2 is a hook called after a variable with a domain is assigned a value. In the simple case where the variable is bound to a concrete value we simply check whether this value is in the domain. Otherwise we take the intersection of the domains and either fail if the intersection is empty (first example), simply assign the value if there is only one value in the intersection (second example) or assign the intersection as the new domain of the variable (third example). The nonterminal attribute_goals/3 is used to translate remaining attributes to user-readable goals that, when executed, reinstate these attributes.

attvar(@Term)
Succeeds if Term is an attributed variable. Note that var/1 also succeeds on attributed variables. Attributed variables are created with put_attr/3.

put_attr(+Var, +Module, +Value)
If Var is a variable or attributed variable, set the value for the attribute named Module to Value. If an attribute with this name is already associated with Var, the old value is replaced. Backtracking will restore the old value (i.e. an attribute is a mutable term. See also setarg/3). This predicate raises a representation error if Var is not a variable and a type error if Module is not an atom.

get_attr(+Var, +Module, -Value)
Request the current value for the attribute named Module. If Var is not an attributed variable or the named attribute is not associated to Var this predicate fails silently. If Module is not an atom, a type error is raised.

del_attr(+Var, +Module)
Delete the named attribute. If Var loses its last attribute it is transformed back into a traditional Prolog variable. If Module is not an atom, a type error is raised. In all other cases this predicate succeeds regardless whether or not the named attribute is present.
attr_unify_hook(+AttValue, +VarValue)

Hook that must be defined in the module an attributed variable refers to. Is is called after the attributed variable has been unified with a non-var term, possibly another attributed variable. *AttValue* is the attribute that was associated to the variable in this module and *VarValue* is the new value of the variable. Normally this predicate fails to veto binding the variable to *VarValue*, forcing backtracking to undo the binding. If *VarValue* is another attributed variable the hook often combines the two attribute and associates the combined attribute with *VarValue* using `put_attr/3`.

attr_portray_hook(+AttValue, +Var)

Called by `write_term/2` and friends for each attribute if the option `attributes(portray)` is in effect. If the hook succeeds the attribute is considered printed. Otherwise `Module = ...` is printed to indicate the existence of a variable.

attribute_goals(+Var, -Gs, +GsRest)

This nonterminal, if it is defined in a module, is used by `copy_term/3` to project attributes of that module to residual goals. It is also used by the toplevel to obtain residual goals after executing a query.

### 6.1.1 Special purpose predicates for attributes

Normal user code should deal with `put_attr/3`, `get_attr/3` and `del_attr/2`. The routines in this section fetch or set the entire attribute list of a variables. Use of these predicates is anticipated to be restricted to printing and other special purpose operations.

get_atts(+Var, -Attributes)

Get all attributes of *Var*. *Attributes* is a term of the form `att(Module, Value, MoreAttributes)`, where `MoreAttributes` is `[]` for the last attribute.

put_atts(+Var, -Attributes)

Set all attributes of *Var*. See `get_atts/2` for a description of `Attributes`.

copy_term(+Term, -Copy, -Gs)

Create a regular term *Copy* as a copy of *Term* (without any attributes), and a list *Gs* of goals that when executed reinstate all attributes onto *Copy*. The nonterminal `attribute_goals/1`, as defined in the modules the attributes stem from, is used to convert attributes to lists of goals.

copy_term_nat(+Term, -Copy)

As `copy_term/2`. Attributes however, are not copied but replaced by fresh variables.

### 6.2 Coroutining

Coroutining deals with having Prolog goals scheduled for execution as soon as some conditions are fulfilled. In Prolog the most commonly used condition is the instantiation (binding) of a variable. Scheduling a goal to execute immediately after a variable is bound can be used to avoid instantiation errors for some built-in predicates (e.g. arithmetic), do work lazy, prevent the binding of a variable to a particular value, etc. Using `freeze/2` for example we can define a variable can only be assigned an even number:
6.2. COROUTINING

?- freeze(X, X mod 2 =:= 0), X = 3

No

freeze(+Var, :Goal)
Delay the execution of Goal until Var is bound (i.e. is not a variable or attributed variable). If Var is bound on entry freeze/2 is equivalent to call/1. The freeze/2 predicate is realised using an attributed variable associated with the module freeze. Use frozen(Var, Goal) to find out whether and which goals are delayed on Var.

frozen(@Var, -Goal)
Unify Goal with the goal or conjunction of goals delayed on Var. If no goals are frozen on Var, Goal is unified to true.

when(@Condition, :Goal)
Execute Goal when Condition becomes true. Condition is one of ==(X, Y), nonvar(X), ground(X), (Cond1, Cond2) or (Cond1, Cond2). See also freeze/2 and dif/2. The implementation can deal with cyclic terms in X and Y.

The when/2 predicate is realised using attributed variable associated with the module when. It is defined in the autoload library when.

dif(@A, @B)
The dif/2 predicate provides a constraint stating that A and B are different terms. If A and B can never unify dif/2 succeeds deterministically. If A and B are identical it fails immediately and finally, if A and B can unify, goals are delayed that prevent A and B to become equal. The dif/2 predicate behaves as if defined by dif(X, Y) :- when(?=(X, Y), X \\= Y). See also ?=/2. The implementation can deal with cyclic terms.

The dif/2 predicate is realised using attributed variable associated with the module dif. It is defined in the autoload library dif.

call_residue_vars(:Goal, -Vars)
Find residual attributed variables left by Goal. This predicate is intended for debugging programs using coroutining or constraints. Consider a program that poses contracting constraints on a variable. Such programs should fail, but sometimes succeed because the constraint solver is too weak to detect the contradiction. Ideally, delayed goals and constraints are all executed at the end of the computation. The meta predicate call_residue_vars/2 finds variables that are given attributes variables or whose attributes are modified1 by Goal, regardless or not whether these variables are reachable from the arguments of Goal.

The predicate has considerable implications. During the execution of Goal, the garbage collector does not reclaim attributed variables. This causes some degradation of GC performance. In a well-behaved program there are no such variables, so the space impact is generally minimal. The actual collection of Vars is implemented using a scan of the trail- and global stacks.

1Tracking modifications is currently not complete and this feature may be dropped completely in future versions.
6.3 Global variables

Global variables are associations between names (atoms) and terms. They differ in various ways from storing information using `assert/1` or `recorda/3`.

- The value lives on the Prolog (global) stack. This implies that lookup time is independent from the size of the term. This is particularly interesting for large data structures such as parsed XML documents or the CHR global constraint store.

- They support both global assignment using `nb_setval/2` and backtrackable assignment using `b_setval/2`.

- Only one value (which can be an arbitrary complex Prolog term) can be associated to a variable at a time.

- Their value cannot be shared among threads. Each thread has its own namespace and values for global variables.

- Currently global variables are scoped globally. We may consider module scoping in future versions.

Both `b_setval/2` and `nb_setval/2` implicitly create a variable if the referenced name does not already refer to a variable.

Global variables may be initialised from directives to make them available during the program lifetime, but some considerations are necessary for saved-states and threads. Saved-states to not store global variables, which implies they have to be declared with `initialization/1` to recreate them after loading the saved state. Each thread has its own set of global variables, starting with an empty set. Using `thread_initialization/1` to define a global variable it will be defined, restored after reloading a saved state and created in all threads that are created after the registration. Finally, global variables can be initialised using the exception hook called `exception/3`. The latter technique is by CHR (see chapter 7).

`b_setval(+Name, +Value)`

Associate the term `Value` with the atom `Name` or replaces the currently associated value with `Value`. If `Name` does not refer to an existing global variable a variable with initial value `[ ]` is created (the empty list). On backtracking the assignment is reversed.

`b_getval(+Name, -Value)`

Get the value associated with the global variable `Name` and unify it with `Value`. Note that this unification may further instantiate the value of the global variable. If this is undesirable the normal precautions (double negation or `copy_term/2`) must be taken. The `b_getval/2` predicate generates errors if `Name` is not an atom or the requested variable does not exist.

`nb_setval(+Name, +Value)`

Associates a copy of `Value` created with `duplicate_term/2` with the atom `Name`. Note that this can be used to set an initial value other than `[ ]` prior to backtrackable assignment.

`nb_getval(+Name, -Value)`

The `nb_getval/2` predicate is a synonym for `b_getval/2`, introduced for compatibility
and symmetry. As most scenarios will use a particular global variable either using non-backtracable or backtrackable assignment, using \texttt{nb_getval/2} can be used to document that the variable is used non-backtracable.

\textbf{nb_linkval(+Name, +Value)}

Associates the term \textit{Value} with the atom \textit{Name} without copying it. This is a fast special-purpose variation of \texttt{nb_setval/2} intended for expert users only because the semantics on backtracking to a point before creating the link are poorly defined for compound terms. The principal term is always left untouched, but backtracking behaviour on arguments is undone if the original assignment was \textit{trailed} and left alone otherwise, which implies that the history that created the term affects the behaviour on backtracking. Please consider the following example:

\begin{verbatim}
demo_nb_linkval :-
    T = nice(N),
    \{ N = world, 
        nb_linkval(myvar, T), 
        fail
    ;  nb_getval(myvar, V), 
        writeln(V)
    \}.
\end{verbatim}

\textbf{nb_current(?Name, ?Value)}

Enumerate all defined variables with their value. The order of enumeration is undefined.

\textbf{nb_delete(+Name)}

Delete the named global variable.

\subsection{Compatibility of SWI-Prolog Global Variables}

Global variables have been introduced by various Prolog implementations recently. The implementation of them in SWI-Prolog is based on hProlog by Bart Demoen. In discussion with Bart it was decided that the semantics if \texttt{hProlog nb_setval/2}, which is equivalent to \texttt{nb_linkval/2} is not acceptable for normal Prolog users as the behaviour is influenced by how built-in predicates constructing terms (\texttt{read/1}, \texttt{=../2}, etc.) are implemented.

GNU-Prolog provides a rich set of global variables, including arrays. Arrays can be implemented easily in SWI-Prolog using \texttt{functor/3} and \texttt{setarg/3} due to the unrestricted arity of compound terms.
This chapter is written by Tom Schrijvers, K.U. Leuven, and adjustments by Jan Wielemaker.

The CHR system of SWI-Prolog is the K.U.Leuven CHR system. The runtime environment is written by Christian Holzbaur and Tom Schrijvers while the compiler is written by Tom Schrijvers. Both are integrated with SWI-Prolog and licensed under compatible conditions with permission from the authors.

The main reference for the K.U.Leuven CHR system is:

On the K.U.Leuven CHR website (http://www.cs.kuleuven.be/~toms/CHR/) you can find more related papers, references and example programs.

7.1 Introduction

Constraint Handling Rules (CHR) is a committed-choice rule-based language embedded in Prolog. It is designed for writing constraint solvers and is particularly useful for providing application-specific constraints. It has been used in many kinds of applications, like scheduling, model checking, abduction, type checking among many others.

CHR has previously been implemented in other Prolog systems (SICStus, Eclipse, Yap), Haskell and Java. This CHR system is based on the compilation scheme and runtime environment of CHR in SICStus.

In this documentation we restrict ourselves to giving a short overview of CHR in general and mainly focus on elements specific to this implementation. For a more thorough review of CHR we refer the reader to [Frühwirth, 1998]. More background on CHR can be found at [Frühwirth, ].

In section 7.2 we present the syntax of CHR in Prolog and explain informally its operational semantics. Next, section 7.3 deals with practical issues of writing and compiling Prolog programs containing CHR. Section 7.4 explains the currently primitive CHR debugging facilities. Section 7.4.3 provides a few useful predicates to inspect the constraint store and section 7.5 illustrates CHR with two example programs. In section 7.6 some compatibility issues with older versions of this system and SICStus’ CHR system. Finally, section 7.7 concludes with a few practical guidelines for using CHR.

7.2 Syntax and Semantics

7.2.1 Syntax

The syntax of CHR rules is the following:
rules --> rule, rules.
rules --> [].

rule --> name, actual_rule, pragma, [atom(.'')].

name --> atom, [atom('@')].
name --> [].

actual_rule --> simplification_rule.
actual_rule --> propagation_rule.
actual_rule --> simpagation_rule.

simplification_rule --> head, [atom('<=>')], guard, body.
propagation_rule --> head, [atom('==>')], guard, body.
simpagation_rule --> head, [atom('\')], head, [atom('<=>')], guard, body.

head --> constraints.

constraints --> constraint, constraint_id.
constraints --> constraint, constraint_id, [atom(',')], constraints.

constraint --> compound_term.

constraint_id --> [].
constraint_id --> [atom('#')], variable.
constraint_id --> [atom('#')], [atom('passive')] .

guard --> [].
guard --> goal, [atom('|')].

body --> goal.

pragma --> [].
pragma --> [atom('pragma')], actual_pragmas.

actual_pragmas --> actual pragma.
actual_pragmas --> actual pragma, [atom(',')], actual_pragmas.
actual pragma --> [atom('passive(')], variable, [atom(')')]].

Note that the guard of a rule may not contain any goal that binds a variable in the head of the rule with a non-variable or with another variable in the head of the rule. It may however bind variables that do not appear in the head of the rule, e.g. an auxiliary variable introduced in the guard.
CHAPTER 7. CHR: CONSTRAINT HANDLING RULES

7.2.2 Semantics

In this subsection the operational semantics of CHR in Prolog are presented informally. They do not differ essentially from other CHR systems.

When a constraint is called, it is considered an active constraint and the system will try to apply the rules to it. Rules are tried and executed sequentially in the order they are written.

A rule is conceptually tried for an active constraint in the following way. The active constraint is matched with a constraint in the head of the rule. If more constraints appear in the head they are looked for among the suspended constraints, which are called passive constraints in this context. If the necessary passive constraints can be found and all match with the head of the rule and the guard of the rule succeeds, then the rule is committed and the body of the rule executed. If not all the necessary passive constraint can be found, the matching fails or the guard fails, then the body is not executed and the process of trying and executing simply continues with the following rules. If for a rule, there are multiple constraints in the head, the active constraint will try the rule sequentially multiple times, each time trying to match with another constraint.

This process ends either when the active constraint disappears, i.e. it is removed by some rule, or after the last rule has been processed. In the latter case the active constraint becomes suspended.

A suspended constraint is eligible as a passive constraint for an active constraint. The other way it may interact again with the rules, is when a variable appearing in the constraint becomes bound to either a non-variable or another variable involved in one or more constraints. In that case the constraint is triggered, i.e. it becomes an active constraint and all the rules are tried.

Rule Types

There are three different kinds of rules, each with their specific semantics:

- simplification
  The simplification rule removes the constraints in its head and calls its body.

- propagation
  The propagation rule calls its body exactly once for the constraints in its head.

- simpagation
  The simpagation rule removes the constraints in its head after the \ and then calls its body. It is an optimization of simplification rules of the form:

  \[ constraints_1, constraints_2 \iff constraints_1, body \]

  Namely, in the simpagation form:

  \[ constraints_1 \setminus constraints_2 \iff body \]

  The constraints \( constraints_1 \) constraints are not called in the body.

Rule Names

Naming a rule is optional and has no semantical meaning. It only functions as documentation for the programmer.

Pragmas

The semantics of the pragmas are:

passive(Identifier)

The constraint in the head of a rule Identifier can only match a passive constraint in that rule. There is an abbreviated syntax for this pragma. Instead of:
... c # Id, ... <=> ... pragma passive(Id)

you can also write

... c # passive, ... <=> ... 

Additional pragmas may be released in the future.

:- chr_option(+Option, +Value)

It is possible to specify options that apply to all the CHR rules in the module. Options are specified with the chr_option/2 declaration:

:- chr_option(Option,Value).

and may appear in the file anywhere after the first constraints declaration.

Available options are:

check_guard_bindings
This option controls whether guards should be checked for (illegal) variable bindings or not. Possible values for this option are on, to enable the checks, and off, to disable the checks. If this option is on, any guard fails when it binds a variable that appears in the head of the rule. When the option is off (default), the behavior of a binding in the guard is undefined.

optimize
This option controls the degree of optimization. Possible values are full, to enable all available optimizations, and off (default), to disable all optimizations. The default is derived from the SWI-Prolog flag optimise, where true is mapped to full. Therefore the command-line option -O provides full CHR optimization. If optimization is enabled, debugging must be disabled.

depbug
This options enables or disables the possibility to debug the CHR code. Possible values are on (default) and off. See section 7.4 for more details on debugging. The default is derived from the Prolog flag generate_debug_info, which is true by default. See -nodebug. If debugging is enabled, optimization must be disabled.

7.3 CHR in SWI-Prolog Programs

7.3.1 Embedding in Prolog Programs

The CHR constraints defined in a .pl file are associated with a module. The default module is user. One should never load different .pl files with the same CHR module name.
7.3.2 Constraint declaration

`:-- chr_constraint(+Specifier)

Every constraint used in CHR rules has to be declared with a `chr_constraint/1` declaration by the `constraint specifier`. For convenience multiple constraints may be declared at once with the same `chr_constraint/1` declaration followed by a comma-separated list of constraint specifiers.

A constraint specifier is, in its compact form, `F/A` where `F` and `A` are respectively the functor name and arity of the constraint, e.g.:

`:-- chr_constraint foo/1.
`:-- chr_constraint bar/2, baz/3.

In its extended form, a constraint specifier is `c(A_1, \ldots, A_n)` where `c` is the constraint’s functor, `n` its arity and the `A_i` are argument specifiers. An argument specifier is a mode, optionally followed by a type. E.g.

`:-- chr_constraint get_value(+,?).
`:-- chr_constraint domain(?int, +list(int)),
     alldifferent(?list(int)).

Modes  A mode is one of:

- The corresponding argument of every occurrence of the constraint is always unbound.
+ The corresponding argument of every occurrence of the constraint is always ground.
? The corresponding argument of every occurrence of the constraint can have any instantiation, which may change over time. This is the default value.

Types  A type can be a user-defined type or one of the built-in types. A type comprises a (possibly infinite) set of values. The type declaration for a constraint argument means that for every instance of that constraint the corresponding argument is only ever bound to values in that set. It does not state that the argument necessarily has to be bound to a value.

The built-in types are:

int  The corresponding argument of every occurrence of the constraint is an integer number.
dense_int  The corresponding argument of every occurrence of the constraint is an integer that can be used as an array index. Note that if this argument takes values in `[0, n]`, the array takes \( O(n) \) space.
float  \ldots a floating point number.
number
  …a number.

natural
  …a positive integer.

any
  The corresponding argument of every occurrence of the constraint can have any type. This is
  the default value.

:- chr_type(+TypeDeclaration)
  User-defined types are algebraic data types, similar to those in Haskell or the discriminated
  unions in Mercury. An algebraic data type is defined using chr_type/1:

  :- chr_type type ---> body.

  If the type term is a functor of arity zero (i.e. one having zero arguments), it names a monomor-
  phic type. Otherwise, it names a polymorphic type; the arguments of the functor must be distinct
  type variables. The body term is defined as a sequence of constructor definitions separated by
  semi-colons.

  Each constructor definition must be a functor whose arguments (if any) are types. Discriminated
  union definitions must be transparent: all type variables occurring in the body must also occur
  in the type.

  Here are some examples of algebraic data type definitions:

  :- chr_type color ---> red ; blue ; yellow ; green.
  :- chr_type tree ---> empty ; leaf(int) ; branch(tree, tree).
  :- chr_type list(T) ---> [] ; [T | list(T)].
  :- chr_type pair(T1, T2) ---> (T1 - T2).

  Each algebraic data type definition introduces a distinct type. Two algebraic data types that
  have the same bodies are considered to be distinct types (name equivalence).

  Constructors may be overloaded among different types: there may be any number of construc-
  tors with a given name and arity, so long as they all have different types.

  Aliases can be defined using ==. For example, if your program uses lists of lists of integers,
  you can define an alias as follows:

  :- chr_type lli == list(list(int)).
Type Checking  Currently two complementary forms of type checking are performed:

1. Static type checking is always performed by the compiler. It is limited to CHR rule heads and CHR constraint calls in rule bodies.

Two kinds of type error are detected. The first is where a variable has to belong to two types. For example, in the program:

```prolog
:-chr_type foo ---> foo.
:-chr_type bar ---> bar.
:-chr_constraint abc(?foo).
:-chr_constraint def(?bar).
foobar @ abc(X) <=> def(X).
```

the variable \(X\) has to be of both type \(foo\) and \(bar\). This is reported by the type clash error:

CHR compiler ERROR:

```
'---> Type clash for variable _G5398 in rule foobar:
    expected type foo in body goal def(_G5398, _G5448)
    expected type bar in head def(_G5448, _G5398)
```

The second kind of error is where a functor is used that does not belong to the declared type. E.g. for the program:

```prolog
:-chr_type foo ---> foo.
:-chr_type bar ---> bar.
:-chr_constraint abc(?foo).
foo @ abc(bar) <=> true.
```

in the head of the rule \(bar\) appears where something of type \(foo\) is expected. This is reported as:

CHR compiler ERROR:

```
'---> Invalid functor in head abc(bar) of rule foo:
    found 'bar',
    expected type 'foo'!
```

No runtime overhead is incurred in static type checking.

2. Dynamic type checking checks at runtime, during program execution, whether the arguments of CHR constraints respect their declared types. The when/2 co-routining library is used to delay dynamic type checks until variables are instantiated.

The kind of error detected by dynamic type checking is where a functor is used that does not belong to the declared type. E.g. for the program:
we get the following error in an erroneous query:

?- abc(bar).
ERROR: Type error: ‘foo’ expected, found ‘bar’ (CHR Runtime Type Error)

Dynamic type checking is weaker than static type checking in the sense that it only checks the particular program execution at hand rather than all possible executions. It is stronger in the sense that it tracks types throughout the whole program.

Note that it is enabled only in debug mode, as it incurs some (minor) runtime overhead.

### 7.3.3 Compilation

The SWI-Prolog CHR compiler exploits term_expansion/2 rules to translate the constraint handling rules to plain Prolog. These rules are loaded from the library chr. They are activated if the compiled file has the .chr extension or after finding a declaration of the format below.

```prolog
:- chr_constraint ... 
```

It is advised to define CHR rules in a module file, where the module declaration is immediately followed by including the library(chr) library as exemplified below:

```prolog
:- module(zebra, [ zebra/0 ]).
:- use_module(library(chr)).
:- chr_constraint ... 
```

Using this style CHR rules can be defined in ordinary Prolog .pl files and the operator definitions required by CHR do not leak into modules where they might cause conflicts.

### 7.4 Debugging

The CHR debugging facilities are currently rather limited. Only tracing is currently available. To use the CHR debugging facilities for a CHR file it must be compiled for debugging. Generating debug info is controlled by the CHR option debug, whose default is derived from the SWI-Prolog flag generate_debug_info. Therefore debug info is provided unless the -nodebug is used.

#### 7.4.1 Ports

For CHR constraints the four standard ports are defined:

- **call**
  - A new constraint is called and becomes active.
exit
An active constraint exits: it has either been inserted in the store after trying all rules or has been removed from the constraint store.

fail
An active constraint fails.

redo
An active constraint starts looking for an alternative solution.

In addition to the above ports, CHR constraints have five additional ports:

wake
A suspended constraint is woken and becomes active.

insert
An active constraint has tried all rules and is suspended in the constraint store.

remove
An active or passive constraint is removed from the constraint store.

try
An active constraints tries a rule with possibly some passive constraints. The try port is entered just before committing to the rule.

apply
An active constraints commits to a rule with possibly some passive constraints. The apply port is entered just after committing to the rule.

7.4.2 Tracing

Tracing is enabled with the chr_trace/0 predicate and disabled with the chr_notrace/0 predicate.

When enabled the tracer will step through the call, exit, fail, wake and apply ports, accepting debug commands, and simply write out the other ports.

The following debug commands are currently supported:

CHR debug options:

  <cr>  creep  c  creep
  s     skip
  g     ancestors
  n     nodebug
  b     break
  a     abort
  f     fail
  ?     help  h  help

Their meaning is:
7.4. DEBUGGING

creep
Step to the next port.

skip
Skip to exit port of this call or wake port.

ancestors
Print list of ancestor call and wake ports.

nodebug
Disable the tracer.

break
Enter a recursive Prolog top-level. See break/0.

abort
Exit to the top-level. See abort/0.

fail
Insert failure in execution.

help
Print the above available debug options.

7.4.3 CHR Debugging Predicates

The chr module contains several predicates that allow inspecting and printing the content of the constraint store.

chr_trace
Activate the CHR tracer. By default the CHR tracer is activated and deactivated automatically by the Prolog predicates trace/0 and notrace/0.

chr_notrace
De-activate the CHR tracer. By default the CHR tracer is activated and deactivated automatically by the Prolog predicates trace/0 and notrace/0.

chr_leash(+Spec)
Define the set of CHR ports on which the CHR tracer asks for user intervention (i.e. stops). Spec is either a list of ports as defined in section 7.4.1 or a predefined ‘alias’. Defined aliases are: full to stop at all ports, none or off to never stop, and default to stop at the call, exit, fail, wake and apply ports. See also leash/1.

chr_show_store(+Mod)
Prints all suspended constraints of module Mod to the standard output. This predicate is automatically called by the SWI-Prolog top-level at the end of each query for every CHR module currently loaded. The Prolog flag chr_toplevel_show_store controls whether the top-level shows the constraint stores. The value true enables it. Any other value disables it.

find_chr_constraint(-Constraint)
Returns a constraint in the constraint store. Via backtracking, all constraints in the store can be enumerated.
7.5 Examples

Here are two example constraint solvers written in CHR.

- The program below defines a solver with one constraint, \texttt{leq/2/}, which is a less-than-or-equal constraint, also known as a partial order constraint.

\begin{verbatim}
:- module(leq,[leq/2]).
:- use_module(library(chr)).

:- chr_constraint leq/2.
reflexivity @ leq(X,X) <=> true.
antisymmetry @ leq(X,Y), leq(Y,X) <=> X = Y.
idempotence @ leq(X,Y) \ leq(X,Y) <=> true.
transitivity @ leq(X,Y), leq(Y,Z) ==> leq(X,Z).
\end{verbatim}

When the above program is saved in a file and loaded in SWI-Prolog, you can call the \texttt{leq/2} constraints in a query, e.g.:

\begin{verbatim}
?- leq(X,Y), leq(Y,Z).
leq(_G23837, _G23841)
leq(_G23838, _G23841)
leq(_G23837, _G23838)
X = _G23837{leq = ...}
Y = _G23838{leq = ...}
Z = _G23841{leq = ...}
Yes
\end{verbatim}

When the query succeeds, the SWI-Prolog top-level prints the content of the CHR constraint store and displays the bindings generate during the query. Some of the query variables may have been bound to attributed variables, as you see in the above example.

- The program below implements a simple finite domain constraint solver.

\begin{verbatim}
:- module(dom,[dom/2]).
:- use_module(library(chr)).

:- chr_constraint dom(?int,+list(int)).
:- chr_type list(T) ---> []; [T|list(T)].
dom(X,[]) <=> fail.
dom(X,[Y]) <=> X = Y.
dom(X,L) <=> nonvar(X) | memberchk(X,L).
dom(X,L1), dom(X,L2) <=> intersection(L1,L2,L3), dom(X,L3).
\end{verbatim}
When the above program is saved in a file and loaded in SWI-Prolog, you can call the `dom/2` constraints in a query, e.g.:

```
?- dom(A,[1,2,3]), dom(A,[3,4,5]).
A = 3
Yes
```

### 7.6 Backwards Compatibility

#### 7.6.1 The Old SICStus CHR implementation

There are small differences between the current K.U.Leuven CHR system in SWI-Prolog, older versions of the same system and SICStus’ CHR system.

The current system maps old syntactic elements onto new ones and ignores a number of no longer required elements. However, for each a *deprecated* warning is issued. You are strongly urged to replace or remove deprecated features.

Besides differences in available options and pragmas, the following differences should be noted:

- *The constraints/1 declaration*
  This declaration is deprecated. It has been replaced with the `chr_constraint/1` declaration.

- *The option/2 declaration*
  This declaration is deprecated. It has been replaced with the `chr_option/2` declaration.

- *The handler/1 declaration*
  In SICStus every CHR module requires a `handler/1` declaration declaring a unique handler name. This declaration is valid syntax in SWI-Prolog, but will have no effect. A warning will be given during compilation.

- *The rules/1 declaration*
  In SICStus, for every CHR module it is possible to only enable a subset of the available rules through the `rules/1` declaration. The declaration is valid syntax in SWI-Prolog, but has no effect. A warning is given during compilation.

- *Guard bindings*
  The `check_guard_bindings` option only turns invalid calls to unification into failure. In SICStus this option does more: it intercepts instantiation errors from Prolog built-ins such as `is/2` and turns them into failure. In SWI-Prolog, we do not go this far, as we like to separate concerns more. The CHR compiler is aware of the CHR code, the Prolog system and programmer should be aware of the appropriate meaning of the Prolog goals used in guards and bodies of CHR rules.
7.6.2 The Old ECLiPSe CHR implementation

The old ECLiPSe CHR implementations features a `label_with/1` construct for labeling variables in CHR constraints. This feature has long since been abandoned. However, a simple transformation is all that is required to port the functionality.

```prolog
label_with Constraint1 if Condition1.
...
label_with ConstraintN if ConditionN.
Constraint1 :- Body1.
...
ConstraintN :- BodyN.
```

is transformed into

```prolog
:- chr_constraint my_labeling/0.

my_labeling \ Constraint1 <=> Condition1 | Body1.
...
my_labeling \ ConstraintN <=> ConditionN | BodyN.
my_labeling <=> true.
```

Be sure to put this code after all other rules in your program! With `my_labeling/0` (or another predicate name of your choosing) the labeling is initiated, rather than ECLiPSe’s `chr_labeling/0`.

7.7 Programming Tips and Tricks

In this section we cover several guidelines on how to use CHR to write constraint solvers and how to do so efficiently.

- **Check guard bindings yourself**
  It is considered bad practice to write guards that bind variables of the head and to rely on the system to detect this at runtime. It is inefficient and obscures the working of the program.

- **Set semantics**
  The CHR system allows the presence of identical constraints, i.e. multiple constraints with the same functor, arity and arguments. For most constraint solvers, this is not desirable: it affects efficiency and possibly termination. Hence appropriate simpagation rules should be added of the form:

  ```prolog
  constraint \ constraint <=> true
  ```

- **Multi-headed rules**
  Multi-headed rules are executed more efficiently when the constraints share one or more variables.

- **Mode and type declarations**
  Provide mode and type declarations to get more efficient program execution. Make sure to disable debug (`-nodebug`) and enable optimization (`-O`).
• **Compile once, run many times**
  Does consulting your CHR program take a long time in SWI-Prolog? Probably it takes the CHR compiler a long time to compile the CHR rules into Prolog code. When you disable optimizations the CHR compiler will be a lot quicker, but you may lose performance. Alternatively, you can just use SWI-Prolog’s `qcompile/1` to generate a `.qlf` file once from your `.pl` file. This `.qlf` file contains the generated code of the CHR compiler (be it in a binary format). When you consult the `.qlf` file, the CHR compiler is not invoked and consultation is much faster.

• **Finding Constraints**
  The `find_chr_constraint/1` predicate is fairly expensive. Avoid it, if possible. If you must use it, try to use it with an instantiated toplevel constraint symbol.

### 7.8 Compiler Errors and Warnings

In this section we summarize the most important error and warning messages of the CHR compiler.

#### 7.8.1 CHR Compiler Errors

**Type clash** for variable ... in rule ...

This error indicates an inconsistency between declared types; a variable should belong to two types. See static type checking.

**Invalid functor** in head ... of rule ...

This error indicates an inconsistency between a declared type and the use of a functor in a rule. See static type checking.

**Cyclic alias** definition: ... == ...

You have defined a type alias in terms of itself, either directly or indirectly.

**Ambiguous type aliases** You have defined two overlapping type aliases.

**Multiple definitions** for type

You have defined the same type multiple times.

**Non-ground type** in constraint definition: ...

You have declared a non-ground type for a constraint argument.

**Could not find type definition** for ...

You have used an undefined type in a type declaration.

**Illegal mode/type declaration** You have used invalid syntax in a constraint declaration.

**Constraint multiply defined** There is more than one declaration for the same constraint.

**Undeclared constraint** ... in head of ...

You have used an undeclared constraint in the head of a rule. This often indicates a misspelled constrained name or wrong number of arguments.
**Invalid pragma** ... in ... Pragma should not be a variable.

You have used a variable as a pragma in a rule. This is not allowed.

**Invalid identifier** ... in pragma passive in ...

You have used an identifier in a passive pragma that does not correspond to an identifier in the head of the rule. Likely the identifier name is misspelled.

**Unknown pragma** ... in ...

You have used an unknown pragma in a rule. Likely the pragma is misspelled or not supported.

**Something unexpected** happened in the CHR compiler

You have most likely bumped into a bug in the CHR compiler. Please contact Tom Schrijvers to notify him of this error.
Multi-threaded applications

SWI-Prolog multithreading is based on standard C-language multithreading support. It is not like ParLog or other parallel implementations of the Prolog language. Prolog threads have their own stacks and only share the Prolog heap: predicates, records, flags and other global non-backtrackable data. SWI-Prolog thread support is designed with the following goals in mind.

- **Multi-threaded server applications**
  Today’s computing services often focus on (internet) server applications. Such applications often have need for communication between services and/or fast non-blocking service to multiple concurrent clients. The shared heap provides fast communication and thread creation is relatively cheap.¹

- **Interactive applications**
  Interactive applications often need to perform extensive computation. If such computations are executed in a new thread, the main thread can process events and allow the user to cancel the ongoing computation. User interfaces can also use multiple threads, each thread dealing with input from a distinct group of windows. See also section 8.8.

- **Natural integration with foreign code**
  Each Prolog thread runs in a native thread of the operating system, automatically making them cooperate with MT-safe foreign-code. In addition, any foreign thread can create its own Prolog engine for dealing with calling Prolog from C-code.

SWI-Prolog multi-threading is based on the POSIX thread standard [Butenhof, 1997] used on most popular systems except for MS-Windows. On Windows it uses the pthread-win32 emulation of POSIX threads mixed with the Windows native API for smoother and faster operation.

### 8.1 Creating and destroying Prolog threads

**thread_create(ːGoal, -Id, +Options)**
Create a new Prolog thread (and underlying C-thread) and start it by executing Goal. If the thread is created successfully, the thread-identifier of the created thread is unified to Id. Options is a list of options. The currently defined options are below. Stack size options can also take the value \texttt{inf} or \texttt{infinite}, which is mapped to the maximum stack size supported by the platform.

**alias(AliasName)**
Associate an ‘alias-name’ with the thread. This named may be used to refer to the thread and remains valid until the thread is joined (see thread.join/2).

¹On an dual AMD-Athlon 1600, SWI-Prolog 5.1.0 creates and joins 4,957 threads per second elapsed time.
argument(K-Bytes)
Set the limit to which the argument stack of this thread may grow. If omitted, the limit of the calling thread is used. See also the −A command-line option.

at_exit(AtExit)
Register AtExit as using thread_at_exit/1 before entering the thread goal. Unlike calling thread_at_exit/1 as part of the normal Goal, this ensures the Goal is called. Using thread_at_exit/1, the thread may be signalled or run out of resources before thread_at_exit/1 is reached.

detached(Bool)
If false (default), the thread can be waited for using thread_join/2. thread_join/2 must be called on this thread to reclaim the all resources associated to the thread. If true, the system will reclaim all associated resources automatically after the thread finishes. Please note that thread identifiers are freed for reuse after a detached thread finishes or a normal thread has been joined. See also thread_join/2 and thread_detach/1.
If a detached thread dies due to failure or exception of the initial goal the thread prints a message using print_message/2. If such termination is considered normal the code must be wrapped using ignore/1 and/or catch/3 to ensure successful completion.

global(K-Bytes)
Set the limit to which the global stack of this thread may grow. If omitted, the limit of the calling thread is used. See also the −G command-line option.

local(K-Bytes)
Set the limit to which the local stack of this thread may grow. If omitted, the limit of the calling thread is used. See also the −L command-line option.

stack(K-Bytes)
Set the limit to which the system stack of this thread may grow. The default, minimum and maximum values are system-dependant.

trail(K-Bytes)
Set the limit to which the trail stack of this thread may grow. If omitted, the limit of the calling thread is used. See also the −T command-line option.

The Goal argument is copied to the new Prolog engine. This implies further instantiation of this term in either thread does not have consequences for the other thread: Prolog threads do not share data from their stacks.

thread_self(-Id)
Get the Prolog thread identifier of the running thread. If the thread has an alias, the alias-name is returned.

thread_join(+Id, -Status)
Wait for the termination of thread with given Id. Then unify the result-status of the thread with Status. After this call, Id becomes invalid and all resources associated with the thread are reclaimed. Note that threads with the attribute detached(true) cannot be joined. See also thread_property/2.
A thread that has been completed without thread_join/2 being called on it is partly reclaimed: the Prolog stacks are released and the C-thread is destroyed. A small data-structure
representing the exit-status of the thread is retained until \texttt{thread\_join/2} is called on the thread. Defined values for \texttt{Status} are:

\begin{itemize}
\item \texttt{true}
  The goal has been proven successfully.
\item \texttt{false}
  The goal has failed.
\item \texttt{exception(Term)}
  The thread is terminated on an exception. See \texttt{print\_message/2} to turn system exceptions into readable messages.
\item \texttt{exited(Term)}
  The thread is terminated on \texttt{thread\_exit/1} using the argument \texttt{Term}.
\end{itemize}

\texttt{thread\_detach(+Id)}
\begin{description}
\item Switch thread into detached-state (see detached(\texttt{Bool}) option at \texttt{thread\_create/3}) at runtime. \texttt{Id} is the identifier of the thread placed in detached state. This may be the result of \texttt{PL\_thread\_self/1}.
\end{description}

One of the possible applications is to simplify debugging. Threads that are created as \texttt{detached} leave no traces if they crash. For not-detached threads the status can be inspected using \texttt{thread\_property/2}. Threads nobody is waiting for may be created normally and detach themselves just before completion. This way they leave no traces on normal completion and their reason for failure can be inspected.

\texttt{thread\_exit(+Term)} \hspace{1cm} \texttt{[deprecated]}
\begin{description}
\item Terminates the thread immediately, leaving \texttt{exited(Term)} as result-state for \texttt{thread\_join/2}. If the thread has the attribute \texttt{detached(true)} it terminates, but its exit status cannot be retrieved using \texttt{thread\_join/2} making the value of \texttt{Term} irrelevant. The Prolog stacks and C-thread are reclaimed.
\item The current implementation does not guarantee proper releasing of all mutexes and proper cleanup in \texttt{call\_cleanup/2}, etc. Please use the exception mechanism (\texttt{throw/1}) to abort execution using non-standard control.
\end{description}

\texttt{thread\_initialization(:Goal)}
\begin{description}
\item Run \texttt{Goal} when thread is started. This predicate must be compared with \texttt{initialization/1}, but is intended for initialization operations of the runtime stacks, such as setting global variables as described in section \ref{sec:runtime}. \texttt{Goal} is run on four occasions: at the call to this predicate, after loading a saved state, on starting a new thread and on creating a Prolog engine through the C interface. On loading a saved state, \texttt{Goal} is executed \texttt{after} running the \texttt{initialization/1} hooks.
\end{description}

\texttt{thread\_at\_exit(:Goal)}
\begin{description}
\item Run \texttt{Goal} just before releasing the thread resources. This is to be compared to \texttt{at\_halt/1}, but only for the current thread. These hooks are ran regardless of why the execution of the thread has been completed. As these hooks are run, the return-code is already available through \texttt{thread\_property/2} using the result of \texttt{thread\_self/1} as thread-identifier. See also the \texttt{at\_exit(Goal)} argument of \texttt{thread\_create/3}.
\end{description}
thread_setconcurrency(-Old, +New)

Determine the concurrency of the process, which is defined as the maximum number of concurrently active threads. ‘Active’ here means they are using CPU time. This option is provided if the thread-implementation provides pthread_setconcurrency(). Solaris is a typical example of this family. On other systems this predicate unifies Old to 0 (zero) and succeeds silently.

8.2 Monitoring threads

Normal multi-threaded applications should not need these the predicates from this section because almost any usage of these predicates is unsafe. For example checking the existence of a thread before signalling it is of no use as it may vanish between the two calls. Catching exceptions using catch/3 is the only safe way to deal with thread-existence errors.

These predicates are provided for diagnosis and monitoring tasks. See also section 8.5, describing more high-level primitives.

thread_property(?Id, ?Property)

True if thread Id has Property. Either or both arguments may be unbound, enumerating all relations on backtracking. Calling thread_property/2 does not influence any thread. See also thread_join/2. For threads that have an alias-name, this name is returned in Id instead of the numerical thread identifier. Defined properties are:

alias(Alias)

Alias is the alias name of thread Id.

detached(Boolean)

Current detached status of the thread.

status(Status)

Current status of the thread. Status is one of:

running

The thread is running. This is the initial status of a thread. Please note that threads waiting for something are considered running too.

false

The Goal of the thread has been completed and failed.

ture

The Goal of the thread has been completed and succeeded.

exited(Term)

The Goal of the thread has been terminated using thread_exit/1 with Term as argument. If the underlying native thread has exited (using pthread_exit()) Term is unbound.

exception(Term)

The Goal of the thread has been terminated due to an uncaught exception (see throw/1 and catch/3).

thread_statistics(+Id, +Key, -Value)

Obtains statistical information on thread Id as statistics/2 does in single-threaded appli-
8.3. THREAD COMMUNICATION

This call supports all keys of statistics/2, although only stack sizes and CPU
time yield different values for each thread.²

mutex_statistics
Print usage statistics on internal mutexes and mutexes associated with dynamic predicates.
For each mutex two numbers are printed: the number of times the mutex was acquired and
the number of collisions: the number times the calling thread has to wait for the mutex. The
collision-count is not available on MS-Windows. Generally collision count is close to zero on
single-CPU hardware.

8.3 Thread communication

8.3.1 Message queues

Prolog threads can exchange data using dynamic predicates, database records, and other globally
shared data. These provide no suitable means to wait for data or a condition as they can only be
checked in an expensive polling loop. Message queues provide a means for threads to wait for data or
conditions without using the CPU.

Each thread has a message-queue attached to it that is identified by the thread. Additional queues
are created using message_queue_create/1.

thread_send_message(+QueueOrThreadId, +Term)
Place Term in the given queue or default queue of the indicated thread (which can even be the
message queue of itself (see thread_self/1). Any term can be placed in a message queue,
but note that the term is copied to the receiving thread and variable-bindings are thus lost. This
call returns immediately.

If more than one thread is waiting for messages on the given queue and at least one of these
is waiting with a partially instantiated Term, the waiting threads are all sent a wake-up signal,
starting a rush for the available messages in the queue. This behaviour can seriously harm
performance with many threads waiting on the same queue as all-but-the-winner perform a
useless scan of the queue. If there is only one waiting thread or all waiting threads wait with an
unbound variable an arbitrary thread is restarted to scan the queue.³

thread_get_message(?Term)
Examines the thread message queue and if necessary blocks execution until a term that unifies
to Term arrives in the queue. After a term from the queue has been unified to Term, the term is
deleted from the queue.

Please note that not-unifying messages remain in the queue. After the following has been
executed, thread 1 has the term \texttt{b(gnu)} in its queue and continues execution using \texttt{A = gnat}.

\begin{verbatim}
<thread 1>
  thread_get_message(a(A)),
\end{verbatim}

²Getting the CPU-time of a specific thread is not supported on all platforms. On some platforms it returns total process
CPU time instead of the thread CPU time. Thread CPU time is supported on MS-Windows and most recent Linux versions.
³See the documentation for the POSIX thread functions pthread_cond_signal() v.s. pthread_cond_broadcast() for back-
ground information.
<thread 2>
  thread_send_message(Thread_1, b(gnu)),
  thread_send_message(Thread_1, a(gnat)),

See also thread_peek_message/1.

thread_peek_message(?Term)
Examines the thread message-queue and compares the queued terms with Term until one unifies or the end of the queue has been reached. In the first case the call succeeds (possibly instantiating Term. If no term from the queue unifies this call fails.

message_queue_create(?Queue)
If Queue is an atom, create a named queue. To avoid ambiguity of thread_send_message/2, the name of a queue may not be in use as a thread-name. If Queue is unbound an anonymous queue is created and Queue is unified to its identifier.

message_queue_create(-Queue, +Options)
Create a message queue from Options. Defined options are.

alias(+Alias)
Same as message_queue_create(Alias), but according to the ISO draft on Prolog threads.

max_size(+Size)
Maximum number of terms in the queue. If this number is reached, thread_send_message/2 will suspend until the queue is drained. The option can be used if the source, sending messages to the queue, is faster than the drain, consuming the messages.

message_queue_destroy(+Queue)
Destroy a message queue created with message_queue_create/1. It is not allowed to destroy the queue of a thread. Neither is it allowed to destroy a queue other threads are waiting for.4

thread_get_message(+Queue, ?Term)
As thread_get_message/1, operating on a given queue. It is allowed (but not advised) to get messages from the queue of other threads.

thread.peek_message(+Queue, ?Term)
As thread.peek_message/1, operating on a given queue. It is allowed to peek into another thread’s message queue, an operation that can be used to check whether a thread has swallowed a message sent to it.

message_queue_property(?Queue, ?Property)
True if Property is a property of Queue. Defined properties are:

alias(Alias)
Queue has the given alias name.

---

4BUG: None of these constraints are properly enforced by the system in the current implementation. It is therefore advised not to delete queues unless you are absolutely sure it is safe.
size(Size)
Queue currently contains Size terms. Note that due to concurrent access the returned value may be outdated before it is returned. It can be used for debugging purposes as well as work distribution purposes.

Explicit message queues are designed with the worker-pool model in mind, where multiple threads wait on a single queue and pick up the first goal to execute. Below is a simple implementation where the workers execute arbitrary Prolog goals. Note that this example provides no means to tell when all work is done. This must be realised using additional synchronisation.

```prolog
% create_workers(+Id, +N)
% Create a pool with given Id and number of workers.
create_workers(Id, N) :-
    message_queue_create(Id),
    forall(between(1, N, _),
        thread_create(do_work(Id), _, [])).

do_work(Id) :-
    repeat,
    thread_get_message(Id, Goal),
    ( catch(Goal, E, print_message(error, E))
      -> true
      ; print_message(error, goal_failed(Goal, worker(Id)))
    ),
    fail.

% work(+Id, +Goal)
% Post work to be done by the pool
work(Id, Goal) :-
    thread_send_message(Id, Goal).
```

### 8.3.2 Signalling threads

These predicates provide a mechanism to make another thread execute some goal as an **interrupt**. Signalling threads is safe as these interrupts are only checked at safe points in the virtual machine. Nevertheless, signalling in multi-threaded environments should be handled with care as the receiving thread may hold a **mutex** (see with_mutex). Signalling probably only makes sense to start debugging threads and to cancel no-longer-needed threads with **throw/1**, where the receiving thread should be designed carefully do handle exceptions at any point.

```prolog
thread_signal(+ThreadId, :Goal)
Make thread ThreadId execute Goal at the first opportunity. In the current implementation, this
```
implies at the first pass through the Call-port. The predicate thread_signal/2 itself places Goal into the signalled-thread’s signal queue and returns immediately.

Signals (interrupts) do not cooperate well with the world of multi-threading, mainly because the status of mutexes cannot be guaranteed easily. At the call-port, the Prolog virtual machine holds no locks and therefore the asynchronous execution is safe.

Goal can be any valid Prolog goal, including throw/1 to make the receiving thread generate an exception and trace/0 to start tracing the receiving thread.

In the Windows version, the receiving thread immediately executes the signal if it reaches a Windows GetMessage() call, which generally happens if the thread is waiting for (user-)input.

8.3.3 Threads and dynamic predicates

Besides queues (section 8.3.1) threads can share and exchange data using dynamic predicates. The multi-threaded version knows about two types of dynamic predicates. By default, a predicate declared dynamic (see dynamic/1) is shared by all threads. Each thread may assert, retract and run the dynamic predicate. Synchronisation inside Prolog guarantees the consistency of the predicate. Updates are logical: visible clauses are not affected by assert/retract after a query started on the predicate. In many cases primitive from section 8.4 should be used to ensure application invariants on the predicate are maintained.

Besides shared predicates, dynamic predicates can be declared with the thread_local/1 directive. Such predicates share their attributes, but the clause-list is different in each thread.

thread_local +Functor/+Arity, ...

This directive is related to the dynamic/1 directive. It tells the system that the predicate may be modified using assert/1, retract/1, etc. during execution of the program. Unlike normal shared dynamic data however each thread has its own clause-list for the predicate. As a thread starts, this clause list is empty. If there are still clauses as the thread terminates these are automatically reclaimed by the system (see also volatile/1). The thread_local property implies the properties dynamic and volatile.

Thread-local dynamic predicates are intended for maintaining thread-specific state or intermediate results of a computation.

It is not recommended to put clauses for a thread-local predicate into a file as in the example below as the clause is only visible from the thread that loaded the source-file. All other threads start with an empty clause-list.

:- thread_local
   foo/1.

foo(gnat).

DISCLAIMER Whether or not this declaration is appropriate in the sense of the proper mechanism to reach the goal is still debated. If you have strong feeling in favour or against, please share them in the SWI-Prolog mailing list.
8.4 Thread synchronisation

All internal Prolog operations are thread-safe. This implies two Prolog threads can operate on the same dynamic predicate without corrupting the consistency of the predicate. This section deals with user-level mutexes (called monitors in ADA or critical-sections by Microsoft). A mutex is a MUTual EXclusive device, which implies at most one thread can hold a mutex.

Mutexes are used to realise related updates to the Prolog database. With ‘related’, we refer to the situation where a ‘transaction’ implies two or more changes to the Prolog database. For example, we have a predicate address/2, representing the address of a person and we want to change the address by retracting the old and asserting the new address. Between these two operations the database is invalid: this person has either no address or two addresses, depending on the assert/retract order.

Here is how to realise a correct update:

```prolog
:- initialization
    mutex_create(addressbook).

change_address(Id, Address) :-
    mutex_lock(addressbook),
    retractall(address(Id, _)),
    asserta(address(Id, Address)),
    mutex_unlock(addressbook).
```

**mutex_create(?MutexId)**
Create a mutex. If MutexId is an atom, a named mutex is created. If it is a variable, an anonymous mutex reference is returned. There is no limit to the number of mutexes that can be created.

**mutex_create(-MutexId, +Options)**
Create a mutex using options. Defined options are:

- `alias(Alias)`
  Set the alias name. Using `mutex_create(X, [alias(name)])` is preferred over the equivalent `mutex_create(name)`.

**mutex_destroy(+MutexId)**
Destroy a mutex. After this call, MutexId becomes invalid and further references yield an existence_error exception.

**with_mutex(+MutexId, :Goal)**
Execute Goal while holding MutexId. If Goal leaves choice-points, these are destroyed (as in once/1). The mutex is unlocked regardless of whether Goal succeeds, fails or raises an exception. An exception thrown by Goal is re-thrown after the mutex has been successfully unlocked. See also `mutex_create/1` and `call_cleanup/3`.

Although described in the thread-section, this predicate is also available in the single-threaded version, where it behaves simply as once/1.

**mutex_lock(+MutexId)**
Lock the mutex. Prolog mutexes are recursive mutexes: they can be locked multiple times.
by the same thread. Only after unlocking it as many times as it is locked, the mutex becomes available for locking by other threads. If another thread has locked the mutex the calling thread is suspended until mutex is unlocked.

If MutexId is an atom, and there is no current mutex with that name, the mutex is created automatically using mutex_create/1. This implies named mutexes need not be declared explicitly.

Please note that locking and unlocking mutexes should be paired carefully. Especially make sure to unlock mutexes even if the protected code fails or raises an exception. For most common cases use with_mutex/2, which provides a safer way for handling Prolog-level mutexes. The predicate call_cleanup/[2-3] is another way to guarantee that the mutex is unlocked while retaining non-determinism.

mutex_trylock(+MutexId)
As mutex_lock/1, but if the mutex is held by another thread, this predicate fails immediately.

mutex_unlock(+MutexId)
Unlock the mutex. This can only be called if the mutex is held by the calling thread. If this is not the case, a permission_error exception is raised.

mutex_unlock_all
Unlock all mutexes held by the current thread. This call is especially useful to handle thread-termination using abort/0 or exceptions. See also thread_signal/2.

mutex_property(?MutexId, ?Property)
True if Property is a property of MutexId. Defined properties are:

- alias(Alias)
  Mutex has defined alias name. See mutex_create/2 using the ‘alias’ option.

- status(Status)
  Current status of the mutex. One of unlocked if the mutex is currently not locked or locked(Owner, Count) if mutex is locked Count times by threads Owner. Note that, unless Owner is the calling thread, the locked status can change at any time. There is no useful application of this property, except for diagnostic purposes.5

8.5 Thread-support library(threadutil)

This library defines a couple of useful predicates for demonstrating and debugging multi-threaded applications. This library is certainly not complete.

threads
Lists all current threads and their status.

join_threads
Join all terminated threads. For normal applications, dealing with terminated threads must be part of the application logic, either detaching the thread before termination or making sure it

5BUG: As Owner and Count are fetched separately from the mutex, the values may be inconsistent.
will be joined. The predicate `join_threads/0` is intended for interactive sessions to reclaim resources from threads that died unexpectedly during development.

**interactor**

Create a new console and run the Prolog top-level in this new console. See also `attach_console/0`. In the Windows version a new interactor can also be created from the Run/New thread menu.

### 8.5.1 Debugging threads

Support for debugging threads is still very limited. Debug and trace mode are flags that are local to each thread. Individual threads can be debugged either using the graphical debugger described in section 3.5 (see `tspy/1` and friends) or by attaching a console to the thread and running the traditional command-line debugger (see `attach_console/0`). When using the graphical debugger, the debugger must be *loaded* from the main thread (for example using `guitracer`) before `gtrace/0` can be called from a thread.

**attach_console**

If the current thread has no console attached yet, attach one and redirect the user streams (input, output, and error) to the new console window. On Unix systems the console is an `xterm` application. On Windows systems this requires the GUI version `plwin.exe` rather than the console based `plcon.exe`.

This predicate has a couple of useful applications. One is to separate (debugging) I/O of different threads. Another is to start debugging a thread that is running in the background. If thread 10 is running, the following sequence starts the tracer on this thread:

```prolog
?- thread_signal(10, (attach_console, trace)).
```

**tdebug(+ThreadId)**

Prepare `ThreadId` for debugging using the graphical tracer. This implies installing the tracer hooks in the thread and switching the thread to debug-mode using `debug/0`. The call is injected into the thread using `thread_signal/2`. We refer to the documentation of this predicate for asynchronous interaction with threads. New threads created inherit their debug-mode from the thread that created them.

**tdebug**

Call `tdebug/1` in all running threads.

**tnodebug(+ThreadId)**

Disable debugging thread `ThreadId`.

**tnodebug**

Disable debugging in all threads.

**tspy(:Spec, +ThreadId)**

Set a spy-point as `spy/1` and enable the thread for debugging using `tdebug/1`. Note that a spy-point is a global flag on a predicate that is visible from all threads. Spy points are honoured in all threads that are in debug-mode and ignored in threads that are in nodebug mode.
CHAPTER 8. MULTI-THREADED APPLICATIONS

\texttt{tspy(:Spec)}

Set a spy-point as \texttt{spy/1} and enable debugging in all threads using \texttt{tdebug/0}. Note that removing spy-points can be done using \texttt{nospy/1}. Disabling spy-points in a specific thread is achieved by \texttt{tnodebug/1}.

8.5.2 Profiling threads

In the current implementation, at most one thread can be profiled at any moment. Any thread can call \texttt{profile/1} to profile the execution of some part of its code. The predicate \texttt{tprofile/1} allows for profiling the execution of another thread until the user stops collecting profile data.

\texttt{tprofile(+ThreadId)}

Start collecting profile data in \texttt{ThreadId} and ask the user to hit \texttt{\textasciitilde return} to stop the profiler. See section 4.40 for details on the execution profiler.

8.6 Unbounded thread creation

(SWI-)Prolog threads are rather heavyweight objects, notably on 32-bit systems because each thread uses a considerable amount of \textit{virtual} address space. SWI-Prolog threads claim the stack \textit{limit} in virtual address space for each of the runtime stacks, while on 32-bit systems this resource is generally limited somewhere between 1GB and 3.5 GB, depending on the operating system and operating configuration.

If SWI-Prolog starts a thread it copies the initial goal and starts a POSIX thread which allocates a new Prolog engine that starts proving the given goal. If allocation of the engine fails, typically due to lack of virtual memory space, the thread is still created with minimal (8 Kbyte) stacks and immediately calls its exit handlers. See the option \texttt{at\_exit(Goal)}. Although this mechanism allows for handling this type of error gracefully it is not safe to rely on it. Allocating an engine that nearly exhausts virtual address space may cause failures in normal memory allocation that can appear anywhere in Prolog or the foreign libraries used by it. Such errors typically kill the process with a fatal error.

Especially on 32-bit hardware, the design of the application must consider this issue and avoid ungraceful termination being conservative with the dynamic creation of new threads.

8.7 Multi-threaded mixed C and Prolog applications

All foreign-code linked to the multi-threading version of SWI-Prolog should be thread-safe (\textit{reentrant}) or guarded in Prolog using \texttt{with\_mutex/2} from simultaneous access from multiple Prolog threads. If you want to write mixed multi-threaded C and Prolog application you should first familiarise yourself with writing multi-threaded applications in C (C++)

If you are using SWI-Prolog as an embedded engine in a multi-threaded application you can access the Prolog engine from multiple threads by creating an \textit{engine} in each thread from which you call Prolog. Without creating an engine, a thread can only use functions that do \textit{not} use the \texttt{term\_t} type (for example \texttt{PL\_new\_atom()}).

The system supports two models. Section 8.7.1 describes the original one-to-one mapping. In this schema a native thread attaches a Prolog thread if it needs to call Prolog and detaches is when finished, as opposed to the model from section 8.7.2 where threads temporary use a Prolog engine.
8.7.1 A Prolog thread for each native thread (one-to-one)

In the one-to-one model, the thread that called PL_initialise() has a Prolog engine attached. If another C-thread in the system wishes to call Prolog it must first attach an engine using PL_thread_attach_engine() and call PL_thread_destroy_engine() after all Prolog work is finished. This model is especially suitable with long running threads that need to do Prolog work regularly. See section 8.7.2 for the alternative many-to-many model.

```c
int PL_thread_self()
Returns the integer Prolog identifier of the engine or -1 if the calling thread has no Prolog engine. This function is also provided in the single-threaded version of SWI-Prolog, where it returns -2.
```

```c
int PL_unify_thread_id(term *t, int i)
Unify t with the Prolog thread identifier for thread i. Thread identifiers are normally returned from PL_thread_self(). Returns -1 if the thread does not exist or the unification result.
```

```c
int PL_thread_attach_engine(const PL_thread_attr_t *attr)
Creates a new Prolog engine in the calling thread. If the calling thread already has an engine the reference count of the engine is incremented. The attr argument can be NULL to create a thread with default attributes. Otherwise it is a pointer to a structure with the definition below. For any field with value ‘0’, the default is used. The cancel field may be filled with a pointer to a function that is called when PL_cleanup() terminates the running Prolog engines. If this function is not present or returns FALSE pthread_cancel() is used.
```

```c
typedef struct {
unsigned long local_size; /* Stack sizes (K-bytes) */
unsigned long global_size;
unsigned long trail_size;
unsigned long argument_size;
char * alias; /* alias name */
int (*cancel)(int thread);
} PL_thread_attr_t;
```

The structure may be destroyed after PL_thread_attach_engine() has returned. On success it returns the Prolog identifier for the thread (as returned by PL_thread_self()). If an error occurs, -1 is returned. If this Prolog is not compiled for multi-threading, -2 is returned.

```c
int PL_thread_destroy_engine()
Destroy the Prolog engine in the calling thread. Only takes effect if PL_thread_destroy_engine() is called as many times as PL_thread_attach_engine() in this thread. Returns TRUE on success and FALSE if the calling thread has no engine or this Prolog does not support threads.
```

Please note that construction and destruction of engines are relatively expensive operations. Only destroy an engine if performance is not critical and memory is a critical resource.

```c
int PL_thread_at_exit(void (*function)(void *), void *closure, int global)
Register a handle to be called as the Prolog engine is destroyed. The handler function is called with one void * argument holding closure. If global is TRUE, the handler is installed for all
```
Globally installed handlers are executed after the thread-local handlers. If the handler is installed local for the current thread only (\texttt{global == FALSE}) it is stored in the same FIFO queue as used by \texttt{thread_at_exit/1}.

### 8.7.2 Pooling Prolog engines (many-to-many)

In this model Prolog engines live as entities that are independent from threads. If a thread needs to call Prolog it takes one of the engines from the pool and returns the engine when done. This model is suitable in the following identified cases:

- **Compatibility with the single-threaded version**
  In the single-threaded version, foreign threads must serialise access the one and only thread engine. Functions from this section allow sharing one engine among multiple threads.

- **Many native threads with infrequent Prolog work**
  Prolog threads are expensive in terms of memory and time to create and destroy them. Systems that use a large number of threads that only infrequently need to call Prolog are better take an engine from a pool and return it there.

- **Prolog status must be handed to another thread**
  This situation has been identified by Uwe Lesta when creating a .NET interface for SWI-Prolog. .NET distributes work for active internet connection over a pool of threads. If a Prolog engine contains state for a connection, it must be possible to detach the engine from a thread and re-attach it to another thread handling the same connection.

\begin{verbatim}
PL_engine_t PL_create_engine(PL_thread_attr_t *attributes)
Create a new Prolog engine. \texttt{attributes} is described with \texttt{PL_thread_attach_engine()}. Any thread can make this call after \texttt{PL_initialise()} returned success. The returned engine is not attached to any thread and lives until \texttt{PL_destroy_engine()} is used on the returned handle.

In the single-threaded version this call always returns NULL, indicating failure.

int PL_destroy_engine(PL_engine_t e)
Destroy the given engine. Destroying an engine is only allowed if the engine is not attached to any thread or attached to the calling thread. On success this function returns \texttt{TRUE}, on failure the return value is \texttt{FALSE}.

int PL_set_engine(PL_engine_t engine, PL_engine_t *old)
Make the calling thread ready to use \texttt{engine}. If \texttt{old} is non-NULL the current engine associated with the calling thread is stored at the given location. If \texttt{engine} equals \texttt{PL_ENGINE_MAIN} the initial engine is attached to the calling thread. If \texttt{engine} is \texttt{PL_ENGINE_CURRENT} the engine is not changed. This can be used to query the current engine. This call returns \texttt{PL_ENGINE_SET} if the engine was switched successfully, \texttt{PL_ENGINEINVAL} if \texttt{engine} is not a valid engine handle and \texttt{PL_ENGINE_INUSE} if the engine is currently in use by another thread.

Engines can be changed at any time. For example, it is allowed to select an engine to initiate a Prolog goal, detach it and at a later moment execute the goal from another thread. Note however that the \texttt{term_t}, \texttt{qid_t} and \texttt{fid_t} types are interpreted relative to the engine for which they are created. Behaviour when passing one of these types from one engine to another is undefined.

In the single-threaded version this call only succeeds if \texttt{engine} refers to the main engine.
\end{verbatim}
8.8. MULTITHREADING AND THE XPCE GRAPHICS SYSTEM

Engines in single-threaded SWI-Prolog

In theory it is possible to port the API of section 8.7.2 to the single-threaded version of SWI-Prolog. This allows C-programs to control multiple Prolog engines concurrently. This has not yet been realised.

8.8 Multithreading and the XPCE graphics system

GUI applications written in XPCE can benefit from the multi-threaded version of XPCE/SWI-Prolog if they need to do expensive computations that block to UI in the single-threaded version.

Due to various technical problems on both Windows and Unix/X11 threading is best exploited by handing long computations to their own thread.

The XPCE message passing system is guarded with a single mutex, which synchronises both access from Prolog and activation through the GUI. In MS-Windows, GUI events are processed by the thread that created the window in which the event occurred, whereas in Unix/X11 they are processed by the thread that dispatches messages.

Some tentative work is underway to improve the integration between XPCE and multi-threaded SWI-Prolog. There are two sets of support predicates. The first model assumes that XPCE is running in the main thread and background threads are used for computation. In the second model, XPCE event dispatching runs in the background, while the foreground thread is used for Prolog.

XPCE in the foreground Using XPCE in the foreground simplifies debugging of the UI and generally provides the most comfortable development environment. The GUI creates new threads using thread_create/3 and, after work in the thread is completed, the sub-thread signals the main thread of the completion using in_pce_thread/1.

in_pce_thread(:Goal)

Assuming XPCE is running in the foreground thread, this call gives background threads the opportunity to make calls to the XPCE thread. A call to in_pce_thread/1 succeeds immediately, copying Goal to the XPCE thread. Goal is added to the XPCE event-queue and executed synchronous to normal user events like typing and clicking.

XPCE in the background In this model a thread for running XPCE is created using pce_dispatch/1 and actions are sent to this thread using pce_call/1.

pce_dispatch(+Options)

Create a Prolog thread with the alias-name pce for XPCE event-handling. In the X11 version this call creates a thread that executes the X11 event-dispatch loop. In MS-Windows it creates a thread that executes a windows event-dispatch loop. The XPCE event-handling thread has the alias pce. Options specifies the thread-attributes as thread_create/3.

pce_call(:Goal)

Post Goal to the pce thread, executing it synchronous with the thread’s event-loop. The pce_call/1 predicate returns immediately without waiting. Note that Goal is copied to the pce thread.

For further information about XPCE in threaded applications, please visit http://gollem.science.uva.nl/twiki/pl/bin/view/Development/MultiThreadsXPCE
SWI-Prolog offers a powerful interface to C [Kernighan & Ritchie, 1978]. The main design objectives of the foreign language interface are flexibility and performance. A foreign predicate is a C-function that has the same number of arguments as the predicate represented. C-functions are provided to analyse the passed terms, convert them to basic C-types as well as to instantiate arguments using unification. Non-deterministic foreign predicates are supported, providing the foreign function with a handle to control backtracking.

C can call Prolog predicates, providing both an query interface and an interface to extract multiple solutions from an non-deterministic Prolog predicate. There is no limit to the nesting of Prolog calling C, calling Prolog, etc. It is also possible to write the ‘main’ in C and use Prolog as an embedded logical engine.

9.1 Overview of the Interface

A special include file called SWI-Prolog.h should be included with each C-source file that is to be loaded via the foreign interface. The installation process installs this file in the directory include in the SWI-Prolog home directory (?- current_prolog_flag(home, Home).). This C-header file defines various data types, macros and functions that can be used to communicate with SWI-Prolog. Functions and macros can be divided into the following categories:

- Analysing Prolog terms
- Constructing new terms
- Unifying terms
- Returning control information to Prolog
- Registering foreign predicates with Prolog
- Calling Prolog from C
- Recorded database interactions
- Global actions on Prolog (halt, break, abort, etc.)

9.2 Linking Foreign Modules

Foreign modules may be linked to Prolog in two ways. Using static linking, the extensions, a (short) file defining main() which attaches the extensions calls Prolog and the SWI-Prolog kernel distributed as a C-library are linked together to form a new executable. Using dynamic linking, the extensions
are linked to a shared library (.so file on most Unix systems) or dynamic-link library (.DLL file on Microsoft platforms) and loaded into the running Prolog process.\(^1\)

9.2.1 What linking is provided?

The static linking schema can be used on all versions of SWI-Prolog. Whether or not dynamic linking is supported can be deduced from the Prolog flag open\_shared\_object (see current\_prolog\_flag/2). If this Prolog flag yields true, open\_shared\_object/2 and related predicates are defined. See section 9.4 for a suitable high-level interface to these predicates.

9.2.2 What kind of loading should I be using?

All described approaches have their advantages and disadvantages. Static linking is portable and allows for debugging on all platforms. It is relatively cumbersome and the libraries you need to pass to the linker may vary from system to system, though the utility program plld described in section 9.7 often hides these problems from the user.

Loading shared objects (DLL files on Windows) provides sharing and protection and is generally the best choice. If a saved-state is created using qsave\_program/[1,2], an initialization/1 directive may be used to load the appropriate library at startup.

Note that the definition of the foreign predicates is the same, regardless of the linking type used.

9.3 Dynamic Linking of shared libraries

The interface defined in this section allows the user to load shared libraries (.so files on most Unix systems, .dll files on Windows). This interface is portable to Windows as well as to Unix machines providing dlopen (Solaris, Linux, FreeBSD, Irix and many more) or shl\_open (HP/UX). It is advised to use the predicates from section 9.4 in your application.

open\_shared\_object(+File, -Handle)

File is the name of a shared object file (called dynamic load library in MS-Windows). This file is attached to the current process and Handle is unified with a handle to the library. Equivalent to open\_shared\_object(File, [], Handle). See also load\_foreign\_library/[1,2].

On errors, an exception shared\_object(Action, Message) is raised. Message is the return value from dlerror().

open\_shared\_object(+File, -Handle, +Options)

As open\_shared\_object/2, but allows for additional flags to be passed. Options is a list of atoms. now implies the symbols are resolved immediately rather than lazy (default). global implies symbols of the loaded object are visible while loading other shared objects (by default they are local). Note that these flags may not be supported by your operating system. Check the documentation of dlopen() or equivalent on your operating system. Unsupported flags are silently ignored.

\(^1\)The system also contains code to load .o files directly for some operating systems, notably Unix systems using the BSD a.out executable format. As the number of Unix platforms supporting this gets smaller and this interface is difficult to port and slow, it is no longer described in this manual. The best alternatively would be to use the dld package on machines do not have shared libraries.
close_shared_object(+Handle)
   Detach the shared object identified by Handle.

call_shared_object_function(+Handle, +Function)
   Call the named function in the loaded shared library. The function is called without arguments and the return-value is ignored. Normally this function installs foreign language predicates using calls to PL_register_foreign().

9.4 Using the library shlib for .DLL and .so files

This section discusses the functionality of the (autoload) library shlib.pl, providing an interface to shared libraries. This library can only be used if the Prolog flag open_shared_object is enabled.

load_foreign_library(+Lib, +Entry)
   Search for the given foreign library and link it to the current SWI-Prolog instance. The library may be specified with or without the extension. First, absolute_file_name/3 is used to locate the file. If this succeeds, the full path is passed to the low-level function to open the library. Otherwise, the plain library name is passed, exploiting the operating-system defined search mechanism for the shared library. The file_search_path/2 alias mechanism defines the alias foreign, which refers to the directories ⟨plhome⟩/lib/⟨arch⟩ and ⟨plhome⟩/lib, in this order.

   If the library can be loaded, the function called Entry will be called without arguments. The return value of the function is ignored.

   The Entry function will normally call PL_register_foreign() to declare functions in the library as foreign predicates.

load_foreign_library(+Lib)
   Equivalent to load_foreign_library/2. For the entry-point, this function first identifies the ‘base-name’ of the library, which is defined to be the file-name with path nor extension. It will then try the entry-point install-⟨base⟩. On failure it will try to function install(). Otherwise no install function will be called.

unload_foreign_library(+Lib)
   If the foreign library defines the function uninstall⟨base⟩() or uninstall(), this function will be called without arguments and its return value is ignored. Next, abolish/2 is used to remove all known foreign predicates defined in the library. Finally the library itself is detached from the process.

current_foreign_library(-Lib, -Predicates)
   Query the currently loaded foreign libraries and their predicates. Predicates is a list with elements of the form Module:Head, indicating the predicates installed with PL_register_foreign() when the entry-point of the library was called.

   Figure 9.1 connects a Windows message-box using a foreign function. This example was tested using Windows NT and Microsoft Visual C++ 2.0.
9.4. USING THE LIBRARY SHLIB FOR .DLL AND .SO FILES

```c
#include <windows.h>
#include <SWI-Prolog.h>

static foreign_t
pl_say_hello(term_t to)
{ char *a;

  if ( PL_get_atom_chars(to, &a) )
  { MessageBox(NULL, a, "DLL test", MB_OK|MB_TASKMODAL);
    PL_succeed;
  }

  PL_fail;
}

install_t
install()
{ PL_register_foreign("say_hello", 1, pl_say_hello, 0);
}
```

Figure 9.1: MessageBox() example in Windows NT

9.4.1 Static Linking

Below is an outline of the files structure required for statically linking SWI-Prolog with foreign extensions. `\ldots/pl` refers to the SWI-Prolog home directory (see the Prolog flag `home`). `⟨arch⟩` refers to the architecture identifier that may be obtained using the Prolog flag `arch`.

- `.../pl/runtime/⟨arch⟩/libpl.a` SWI-Library
- `.../pl/include/SWI-Prolog.h` Include file
- `.../pl/include/SWI-Stream.h` Stream I/O include file
- `.../pl/include/SWI-Exports` Export declarations (AIX only)
- `.../pl/include/stub.c` Extension stub

The definition of the foreign predicates is the same as for dynamic linking. Unlike with dynamic linking however, there is no initialisation function. Instead, the file `\ldots/pl/include/stub.c` may be copied to your project and modified to define the foreign extensions. Below is stub.c, modified to link the lowercase example described later in this chapter:

```c
#include <stdio.h>
#include <SWI-Prolog.h>

extern foreign_t pl_lowercase(term, term);

PL_extension predicates[] =
{ /*...*/
```
int
main(int argc, char **argv)
{ PL_register_extensions(predicates);
  if ( !PL_initialise(argc, argv) )
    PL_halt(1);

  PL_install_readline(); /* delete if not required */

  PL_halt(PL_toplevel() ? 0 : 1);
}

Now, a new executable may be created by compiling this file and linking it to libpl.a from the runtime directory and the libraries required by both the extensions and the SWI-Prolog kernel. This may be done by hand, or using the plld utility described in section plld. If the linking is performed ‘by hand’, the command-line option -dump-runtime-variables (see section 2.4) can be used to obtain the required paths, libraries and linking options to link the new executable.

9.5 Interface Data types

9.5.1 Type term_t: a reference to a Prolog term

The principal data-type is term_t. Type term_t is what Quintus calls QP_term_ref. This name indicates better what the type represents: it is a handle for a term rather than the term itself. Terms can only be represented and manipulated using this type, as this is the only safe way to ensure the Prolog kernel is aware of all terms referenced by foreign code and thus allows the kernel to perform garbage-collection and/or stack-shifts while foreign code is active, for example during a callback from C.

A term reference is a C unsigned long, representing the offset of a variable on the Prolog environment-stack. A foreign function is passed term references for the predicate-arguments, one for each argument. If references for intermediate results are needed, such references may be created using PL_new_term_ref() or PL_new_term_refs(). These references normally live till the foreign function returns control back to Prolog. Their scope can be explicitly limited using PL_open_foreign_frame() and PL_discard_foreign_frame().

A term_t always refers to a valid Prolog term (variable, atom, integer, float or compound term). A term lives either until backtracking takes us back to a point before the term was created, the garbage collector has collected the term or the term was created after a PL_open_foreign_frame() and PL_discard_foreign_frame() has been called.

The foreign-interface functions can either read, unify or write to term-references. In the this document we use the following notation for arguments of type term_t:

/*{ "name", arity, function, PL_FA_<flags> },*/

{ "lowercase", 2 pl_lowercase, 0 },
{ NULL, 0, NULL, 0 } /* terminating line */

9.5. INTERFACE DATA TYPES

- **Accessed in read-mode.** The ‘+’ indicates the argument is ‘input’.
- **Accessed in write-mode.**
- **Accessed in unify-mode.**

Term references are obtained in any of the following ways.

- **Passed as argument**
  The C-functions implementing foreign predicates are passed their arguments as term-references. These references may be read or unified. Writing to these variables causes undefined behaviour.

- **Created by PL_new_term_ref()**
  A term created by PL_new_term_ref() is normally used to build temporary terms or be written by one of the interface functions. For example, PL_get_arg() writes a reference to the term-argument in its last argument.

- **Created by PL_new_term_refs(int n)**
  This function returns a set of term refs with the same characteristics as PL_new_term_ref(). See PL_open_query().

- **Created by PL_copy_term_ref(term_t t)**
  Creates a new term-reference to the same term as the argument. The term may be written to. See figure 9.3.

Term-references can safely be copied to other C-variables of type term_t, but all copies will always refer to the same term.

- **term_t PL_new_term_ref()**
  Return a fresh reference to a term. The reference is allocated on the local stack. Allocating a term-reference may trigger a stack-shift on machines that cannot use sparse-memory management for allocation the Prolog stacks. The returned reference describes a variable.

- **term_t PL_new_term_refs(int n)**
  Return n new term references. The first term-reference is returned. The others are \( t + 1 \), \( t + 2 \), etc. There are two reasons for using this function. PL_open_query() expects the arguments as a set of consecutive term references and very time-critical code requiring a number of term-references can be written as:

```c
pl_mypredicate(term_t a0, term_t a1)
{ term_t t0 = PL_new_term_refs(2);
  term_t t1 = t0+1;
  ...
}
```

- **term_t PL_copy_term_ref(term_t from)**
  Create a new term reference and make it point initially to the same term as from. This function is commonly used to copy a predicate argument to a term reference that may be written.
void **\texttt{PL reset term refs}(\texttt{term t after})

Destroy all term references that have been created after \texttt{after}, including \texttt{after} itself. Any reference to the invalidated term references after this call results in undefined behaviour.

Note that returning from the foreign context to Prolog will reclaim all references used in the foreign context. This call is only necessary if references are created inside a loop that never exits back to Prolog. See also \texttt{PL open foreign frame()}, \texttt{PL close foreign frame()} and \texttt{PL discard foreign frame()}.

\textbf{Interaction with the garbage collector and stack-shifter}

Prolog implements two mechanisms for avoiding stack overflow: garbage collection and stack expansion. On machines that allow for it, Prolog will use virtual memory management to detect stack overflow and expand the runtime stacks. On other machines Prolog will reallocate the stacks and update all pointers to them. To do so, Prolog needs to know which data is referenced by C-code. As all Prolog data known by C is referenced through term references (\texttt{term t}), Prolog has all information necessary to perform its memory management without special precautions from the C-programmer.

\section*{9.5.2 Other foreign interface types}

\textbf{atom t} An atom in Prolog's internal representation. Atoms are pointers to an opaque structure. They are a unique representation for represented text, which implies that atom \texttt{A} represents the same text as atom \texttt{B} if-and-only-if \texttt{A} and \texttt{B} are the same pointer.

Atoms are the central representation for textual constants in Prolog The transformation of C a character string to an atom implies a hash-table lookup. If the same atom is needed often, it is advised to store its reference in a global variable to avoid repeated lookup.

\textbf{functor t} A functor is the internal representation of a name/arity pair. They are used to find the name and arity of a compound term as well as to construct new compound terms. Like atoms they live for the whole Prolog session and are unique.

\textbf{predicate t} Handle to a Prolog predicate. Predicate handles live forever (although they can loose their definition).

\textbf{qid t} Query Identifier. Used by \texttt{PL open query()}/\texttt{PL next solution()}/\texttt{PL close query()} to handle backtracking from C.

\textbf{fid t} Frame Identifier. Used by \texttt{PL open foreign frame()}/\texttt{PL close foreign frame()}.

\textbf{module t} A module is a unique handle to a Prolog module. Modules are used only to call predicates in a specific module.

\textbf{foreign t} Return type for a C-function implementing a Prolog predicate.

\textbf{control t} Passed as additional argument to non-deterministic foreign functions. See \texttt{PL retry*()} and \texttt{PL foreign context*()}.

\textbf{install t} Type for the install() and uninstall() functions of shared or dynamic link libraries. See secresfshlib.
int64.t  Actually part of the C99 standard rather than Prolog. As of version 5.5.6, Prolog integers are 64-bit on all hardware. The C99 type int64.t is defined in the stdint.h standard header and provides platform independent 64-bit integers. Portable code accessing Prolog should use this type to exchange integer values. Please note that PL_get_long() can return FALSE on Prolog integers outside the long domain. Robust code should not assume any of the integer fetching functions to succeed if the Prolog term is know to be an integer.

9.6  The Foreign Include File

9.6.1  Argument Passing and Control

If Prolog encounters a foreign predicate at run time it will call a function specified in the predicate definition of the foreign predicate. The arguments 1, . . . , ⟨arity⟩ pass the Prolog arguments to the goal as Prolog terms. Foreign functions should be declared of type foreign.t. Deterministic foreign functions have two alternatives to return control back to Prolog:

(return) foreign.t  PL_succeed()
Succeed deterministically. PL_succeed is defined as return TRUE.

(return) foreign.t  PL_fail()
Fail and start Prolog backtracking. PL_fail is defined as return FALSE.

Non-deterministic Foreign Predicates

By default foreign predicates are deterministic. Using the PL_FA_NONDETERMINISTIC attribute (see PL_register_foreign()) it is possible to register a predicate as a non-deterministic predicate. Writing non-deterministic foreign predicates is slightly more complicated as the foreign function needs context information for generating the next solution. Note that the same foreign function should be prepared to be simultaneously active in more than one goal. Suppose the natural_number_below_n/2 is a non-deterministic foreign predicate, backtracking over all natural numbers lower than the first argument. Now consider the following predicate:

quotient_below_n(Q, N) :-
  natural_number_below_n(N, N1),
  natural_number_below_n(N, N2),
  Q =:= N1 / N2, !.

In this predicate the function natural_number_below_n/2 simultaneously generates solutions for both its invocations.

Non-deterministic foreign functions should be prepared to handle three different calls from Prolog:

• Initial call (PL_FIRST_CALL)
  Prolog has just created a frame for the foreign function and asks it to produce the first answer.

• Redo call (PL_REDO)
  The previous invocation of the foreign function associated with the current goal indicated it was possible to backtrack. The foreign function should produce the next solution.
• Terminate call (PL_CUTTED)
  The choice point left by the foreign function has been destroyed by a cut. The foreign function
  is given the opportunity to clean the environment.

  Both the context information and the type of call is provided by an argument of type control_t
  appended to the argument list for deterministic foreign functions. The macro PL_foreign_control()
  extracts the type of call from the control argument. The foreign function can pass a context han-
  dle using the PL_retry*() macros and extract the handle from the extra argument using the
  PL_foreign_context*() macro.

  (return) foreign_t PL_retry(long)
  The foreign function succeeds while leaving a choice point. On backtracking over this goal
  the foreign function will be called again, but the control argument now indicates it is a
  ‘Redo’ call and the macro PL_foreign_context() returns the handle passed via PL_retry().
  This handle is a 30 bits signed value (two bits are used for status indication). Defined as
  return _PL_retry(n). See also PL_succeed().

  (return) foreign_t PL_retry_address(void *)
  As PL_retry(), but ensures an address as returned by malloc() is correctly recovered by
  PL_foreign_context_address(). Defined as return _PL_retry_address(n). See also
  PL_succeed().

  int PL_foreign_control(control_t)
  Extracts the type of call from the control argument. The return values are described above.
  Note that the function should be prepared to handle the PL_CUTTED case and should be aware
  that the other arguments are not valid in this case.

  long PL_foreign_context(control_t)
  Extracts the context from the context argument. In the call type is PL_FIRST_CALL the context
  value is 0L. Otherwise it is the value returned by the last PL_retry() associated with this goal
  (both if the call type is PL_REDO as PL_CUTTED).

  void * PL_foreign_context_address(control_t)
  Extracts an address as passed in by PL_retry_address().

  Note: If a non-deterministic foreign function returns using PL_succeed or PL_fail, Prolog assumes
  the foreign function has cleaned its environment. No call with control argument PL_CUTTED will
  follow.

  The code of figure 9.2 shows a skeleton for a non-deterministic foreign predicate definition.

9.6.2 Atoms and functors

The following functions provide for communication using atoms and functors.

atom_t PL_new_atom(const char *)
  Return an atom handle for the given C-string. This function always succeeds. The returned
  handle is valid as long as the atom is referenced (see section 9.6.2).
typedef struct /* define a context structure */
{ ...
} context;

foreign_t
my_function(term_t a0, term_t a1, control_t handle)
{ struct context * ctxt;

switch( PL_foreign_control(handle) )
{ case PL_FIRST_CALL:
    ctxt = malloc(sizeof(struct context));
    ...
    PL_retry_address(ctxt);
    case PL_REDO:
    ctxt = PL_foreign_context_address(handle);
    ...
    PL_retry_address(ctxt);
    case PL_CUTTED:
    ctxt = PL_foreign_context_address(handle);
    ...
    PL_retry_address(ctxt);
    free(ctxt);
    PL_succeed;
    } }

Figure 9.2: Skeleton for non-deterministic foreign functions
const char* PL_atom_chars(atom_t atom)

Return a C-string for the text represented by the given atom. The returned text will not be
changed by Prolog. It is not allowed to modify the contents, not even ‘temporary’ as the
string may reside in read-only memory. The returned string becomes invalid if the atom is
garbage-collected (see section 9.6.2). Foreign functions that require the text from an atom
passed in a term_t normally use PL_get_atom_chars() or PL_get_atom_nchars().

functor_t PL_new_functor(atom_t name, int arity)

Returns a functor identifier, a handle for the name/arity pair. The returned handle is valid for
the entire Prolog session.

atom_t PL_functor_name(functor_t f)

Return an atom representing the name of the given functor.

int PL_functor arity(functor_t f)

Return the arity of the given functor.

Atoms and atom-garbage collection

With the introduction of atom-garbage collection in version 3.3.0, atoms no longer live as long as the
process. Instead, their lifetime is guaranteed only as long as they are referenced. In the single-threaded
version, atom garbage collections are only invoked at the call-port. In the multi-threaded version (see
section 8), they appear asynchronously, except for the invoking thread.

For dealing with atom garbage collection, two additional functions are provided:

void PL_register_atom(atom_t atom)

Increment the reference count of the atom by one. PL_new_atom() performs this automatically,
returning an atom with a reference count of at least one.2

void PL_unregister_atom(atom_t atom)

Decrement the reference count of the atom. If the reference-count drops below zero, an asser-
tion error is raised.

Please note that the following two calls are different with respect to atom garbage collection:

PL_unify_atom_chars(t, "text");
PL_unify_atom(t, PL_new_atom("text"));

The latter increments the reference count of the atom text, which effectively ensures the atom will
never be collected. It is advised to use the *.chars() or *.nchars() functions whenever applicable.

9.6.3 Analysing Terms via the Foreign Interface

Each argument of a foreign function (except for the control argument) is of type term_t, an opaque
handle to a Prolog term. Three groups of functions are available for the analysis of terms. The first
just validates the type, like the Prolog predicates var/1, atom/1, etc and are called PL_is_*().
The second group attempts to translate the argument into a C primitive type. These predicates take a
term_t and a pointer to the appropriate C-type and return TRUE or FALSE depending on successful
or unsuccessful translation. If the translation fails, the pointed-to data is never modified.

2Otherwise asynchronous atom garbage collection might destroy the atom before it is used.
Testing the type of a term

int PL_term_type(term_t)
Obtain the type of a term, which should be a term returned by one of the other interface predicates or passed as an argument. The function returns the type of the Prolog term. The type identifiers are listed below. Note that the extraction functions PL_ge_t*() also validate the type and thus the two sections below are equivalent.

if ( PL_is_atom(t) )
{ char *s;
  PL_get_atom_chars(t, &s);
  ...;
}
or
char *s;
if ( PL_get_atom_chars(t, &s) )
{ ...;
}

<table>
<thead>
<tr>
<th>PL_VARIABLE</th>
<th>An unbound variable. The value of term as such is a unique identifier for the variable.</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL_ATOM</td>
<td>A Prolog atom.</td>
</tr>
<tr>
<td>PL_STRING</td>
<td>A Prolog string.</td>
</tr>
<tr>
<td>PL_INTEGER</td>
<td>A Prolog integer.</td>
</tr>
<tr>
<td>PL_FLOAT</td>
<td>A Prolog floating point number.</td>
</tr>
<tr>
<td>PL_TERM</td>
<td>A compound term. Note that a list is a compound term ./2.</td>
</tr>
</tbody>
</table>

The functions PL_is_{type} are an alternative to PL_term_type(). The test PL_is_variable(term) is equivalent to PL_term_type(term) == PL_VARIABLE, but the first is considerably faster. On the other hand, using a switch over PL_term_type() is faster and more readable then using an if-then-else using the functions below. All these functions return either TRUE or FALSE.

int PL_is_variable(term_t)
Returns non-zero if term is a variable.

int PL_is_ground(term_t)
Returns non-zero if term is a ground term. See also ground/1. This function is cycle-safe.

int PL_is_atom(term_t)
Returns non-zero if term is an atom.

int PL_is_string(term_t)
Returns non-zero if term is a string.
int PL_is_integer(term_t)
    Returns non-zero if term is an integer.

int PL_is_float(term_t)
    Returns non-zero if term is a float.

int PL_is_compound(term_t)
    Returns non-zero if term is a compound term.

int PL_is_functor(term_t, functor_t)
    Returns non-zero if term is compound and its functor is functor. This test is equivalent to PL_get_functor(), followed by testing the functor, but easier to write and faster.

int PL_is_list(term_t)
    Returns non-zero if term is a compound term with functor /2 or the atom [].

int PL_is_atomic(term_t)
    Returns non-zero if term is atomic (not variable or compound).

int PL_is_number(term_t)
    Returns non-zero if term is an integer or float.

int PL_is_acyclic(term_t)
    Returns non-zero if term is acyclic (i.e. a finite tree).

Reading data from a term

The functions PL_get_*() read information from a Prolog term. Most of them take two arguments. The first is the input term and the second is a pointer to the output value or a term-reference.

int PL_get_atom(term_t +t, atom_t *a)
    If t is an atom, store the unique atom identifier over a. See also PL_atom_chars() and PL_new_atom(). If there is no need to access the data (characters) of an atom, it is advised to manipulate atoms using their handle. As the atom is referenced by t, it will live at least as long as t does. If longer live-time is required, the atom should be locked using PL_register_atom().

int PL_get_atom_chars(term_t +t, char **s)
    If t is an atom, store a pointer to a 0-terminated C-string in s. It is explicitly not allowed to modify the contents of this string. Some built-in atoms may have the string allocated in read-only memory, so ‘temporary manipulation’ can cause an error.

int PL_get_string_chars(term_t +t, char **s, int *len)
    If t is a string object, store a pointer to a 0-terminated C-string in s and the length of the string in len. Note that this pointer is invalidated by backtracking, garbage-collection and stack-shifts, so generally the only safe operations are to pass it immediately to a C-function that doesn’t involve Prolog.

int PL_get_chars(term_t +t, char **s, unsigned flags)
    Convert the argument term t to a 0-terminated C-string. flags is a bitwise disjunction from two groups of constants. The first specifies which term-types should converted and the second how the argument is stored. Below is a specification of these constants. BUF_RING implies,
if the data is not static (as from an atom), the data is copied to the next buffer from a ring of 16 buffers. This is a convenient way of converting multiple arguments passed to a foreign predicate to C-strings. If BUF_MALLOC is used, the data must be freed using PL_free() when not needed any longer.

With the introduction of wide-characters (see section 2.17.1), not all atoms can be converted into a char*. This function fails if \( t \) is of the wrong type, but also if the text cannot be represented. See the REP_* flags below for details.

| CVT_ATOM | Convert if term is an atom |
| CVT_STRING | Convert if term is a string |
| CVT_LIST | Convert if term is a list of integers between 1 and 255 |
| CVT_INTEGER | Convert if term is an integer (using %d) |
| CVT_FLOAT | Convert if term is a float (using %f) |
| CVT_NUMBER | Convert if term is an integer or float |
| CVT_ATOMIC | Convert if term is atomic |
| CVT_VARIABLE | Convert variable to print-name |
| CVT_WRITE | Convert any term that is not converted by any of the other flags using write/1. If no BUF_* is provided, BUF_RING is implied. |
| CVT_ALL | Convert if term is any of the above, except for CVT_VARIABLE and CVT_WRITE |
| CVT_EXCEPTION | If conversion fails due to a type error, raise a Prolog type error exception in addition to failure |
| BUF_DISCARDABLE | Data must copied immediately |
| BUF_RING | Data is stored in a ring of buffers |
| BUF_MALLOC | Data is copied to a new buffer returned by PL_malloc(3). When no longer needed the user must call PL_free() on the data. |
| REP_ISO_LATIN_1 | (0, default). Text is in ISO Latin-1 encoding and the call fails if text cannot be represented. |
| REP_UTF8 | Convert the text to a UTF-8 string. This works for all text. |
| REP_MB | Convert to default locale-defined 8-bit string. Success depends on the locale. Conversion is done using the wctomb() C-library function. |

```c
int PL_get_list_chars(+term t l, char **s, unsigned flags)
Same as PL_get_chars(l, s, CVT_LIST|flags), provided flags contains no of the CVT_* flags.

int PL_get_integer(+term t t, int *i)
If \( t \) is a Prolog integer, assign its value over \( i \). On 32-bit machines, this is the same as PL_get_long(), but avoids a warning from the compiler. See also PL_get_long().

int PL_get_long(term t +t, long *i)
If \( t \) is a Prolog integer that can be represented as a long, assign its value over \( i \). If \( t \) is an integer that cannot be represented by a C long, this function returns FALSE. If \( t \) is a floating point number that can be represented as a long, this function succeeds as well. See also PL_get_int64()```
### CHAPTER 9. FOREIGN LANGUAGE INTERFACE

```c
int PL_get_int64(term_t *t, int64_t *i)
    If \( t \) is a Prolog integer or float that can be represented as a \texttt{int64_t}, assign its value over \( i \). Currently all Prolog integers can be represented using this type, but this might change if SWI-Prolog introduces unbounded integers.
```

```c
int PL_get_bool(term_t *t, int *val)
    If \( t \) has the value \texttt{true} or \texttt{false}, set \( val \) to the C constant \texttt{TRUE} or \texttt{FALSE} and return success. otherwise return failure.
```

```c
int PL_get_pointer(term_t *t, void **ptr)
    In the current system, pointers are represented by Prolog integers, but need some manipulation to make sure they do not get truncated due to the limited Prolog integer range. \texttt{PL_put_pointer()}/\texttt{PL_get_pointer()} guarantees pointers in the range of \texttt{malloc()} are handled without truncating.
```

```c
int PL_get_float(term_t *t, double *f)
    If \( t \) is a float or integer, its value is assigned over \( f \).
```

```c
int PL_get_functor(term_t *t, functor_t *f)
    If \( t \) is compound or an atom, the Prolog representation of the name-arity pair will be assigned over \( f \). See also \texttt{PL_get_name_arity()} and \texttt{PL_is_functor()}.
```

```c
int PL_get_name_arity(term_t *t, atom_t *name, int *arity)
    If \( t \) is compound or an atom, the functor-name will be assigned over \( name \) and the arity over \( arity \). See also \texttt{PL_get_functor()} and \texttt{PL_is_functor()}.
```

```c
int PL_get_module(term_t *t, module_t *module)
    If \( t \) is an atom, the system will lookup or create the corresponding module and assign an opaque pointer to it over \( module \).
```

```c
int PL_get_arg(int index, term_t *t, term_t *a)
    If \( t \) is compound and index is between 1 and arity (including), assign \( a \) with a term-reference to the argument.
```

```c
int _PL_get_arg(int index, term_t *t, term_t *a)
    Same as \texttt{PL_get_arg()}, but no checking is performed, nor whether \( t \) is actually a term, nor whether \( index \) is a valid argument-index.
```

### Exchanging text using length and string

All internal text-representation of SWI-Prolog is represented using \texttt{char *} plus length and allow for \texttt{0-bytes} in them. The foreign library supports this by implementing a \texttt{*nchars()} function for each applicable \texttt{*chars()} function. Below we briefly present the signatures of these functions. For full documentation consult the \texttt{*chars()} function.

```c
int PL_get_atom_nchars(term_t t, size_t *len, char **s)
    See \texttt{PL_get_atom_chars()}.
```

```c
int PL_get_list_nchars(term_t t, size_t *len, char **s)
    See \texttt{PL_get_list_chars()}.
```
9.6. THE FOREIGN INCLUDE FILE

int PL_get_nchars(term t, size_t *len, char **s, unsigned int flags)
    See PL_get_chars().

int PL_put_atom_nchars(term t, size_t len, const char *s)
    See PL_put_atom_chars().

int PL_put_string_nchars(term t, size_t len, const char *s)
    See PL_put_string_chars().

int PL_put_list_ncodes(term t, size_t len, const char *s)
    See PL_put_list_codes().

int PL_put_list_nchars(term t, size_t len, const char *s)
    See PL_put_list_chars().

int PL_unify_atom_nchars(term t, size_t len, const char *s)
    See PL_unify_atom_chars().

int PL_unify_string_nchars(term t, size_t len, const char *s)
    See PL_unify_string_chars().

int PL_unify_list_ncodes(term t, size_t len, const char *s)
    See PL_unify_list_codes().

int PL_unify_list_nchars(term t, size_t len, const char *s)
    See PL_unify_list_chars().

In addition, the following functions are available for creating and inspecting atoms:

atom_t PL_new_atom_nchars(size_t len, const char *s)
    Create a new atom as PL_new_atom(), but from length and characters.

const char * PL_atom_nchars(atom t a, size_t *len)
    Extract text and length of an atom.

Wide character versions

Support for exchange of wide character strings is still under consideration. The functions dealing with 8-bit character strings return failure when operating on a wide character atom or Prolog string object. The functions below can extract and unify both 8-bit and wide atoms and string objects. Wide character strings are represented as C arrays of objects of the type pl_wchar_t, which is guaranteed to be the same as wchar_t on platforms supporting this type. For example, on MS-Windows, this represents 16-bit UCS2 characters, while using the GNU C library (glibc) this represents 32-bit UCS4 characters.

atom_t PL_new_atom_wchars(size_t len, const pl_wchar *s)
    Create atom from wide-character string as PL_new_atom_nchars() does for ISO-Latin-1 strings. If s only contains ISO-Latin-1 characters a normal byte-array atom is created.
pl wchar t * PL Atom Wchars(atom t atom, int * len)
Extract characters from a wide-character atom. Fails (returns NULL) if atom is not a wide-
character atom. This is the wide-character version of PL Atom Nchars(). Note that only one
of these functions succeeds on a particular atom. Especially, after creating an atom with
PL New Atom Wchars(), extracting the text using PL Atom Wchars() will fail if the atom only
contains ISO-Latin-1 characters.

int PL Get Wchars(term t, size t * len, pl wchar t ** s, unsigned flags)
Wide-character version of PL GetChars(). The flags argument is the same as for PL GetChars().

int PL Unify Wchars(term t, int type, size t len, const pl wchar t * s)
Unify t with a textual representation of the C wide character array s. The argtype argument
defines the Prolog representation and is one of PL Atom, PL STRING, PL CODE LIST or
PL CHAR LIST.

int PL Unify Wchars Diff(term t + t, term t - tail, int type, size t len, const pl wchar t * s)
Difference list version of PL Unify Wchars(), only supporting the types PL CODE LIST and
PL CHAR LIST. It serves two purposes. It allows for returning very long lists from data
read from a stream without the need for a resizing buffer in C. Also, the use of differ-
ence lists is often practical for further processing in Prolog. Examples can be found in
packages/plib/readutil.c from the source distribution.

Reading a list
The functions from this section are intended to read a Prolog list from C. Suppose we expect a list of
atoms, the following code will print the atoms, each on a line:

foreign_t
pl_write_atoms(term t l)
{ term t head = PL New Term Ref(); /* variable for the elements */
 term t list = PL Copy Term Ref(l); /* copy as we need to write */

 while( PL Get List(list, head, list) )
 { char * s;

 if ( PL Get Atom Chars(head, & s) )
 sprintf("%s\n", s);
 else
 PL fail;
 }

 return PL Get Nil(list); /* test end for [] */
 }

int PL Get List(term t + l, term t - h, term t - t)
If l is a list and not [] assign a term-reference to the head to h and to the tail to t.

int PL Get Head(term t + l, term t - h)
If l is a list and not [] assign a term-reference to the head to h.
9.6. THE FOREIGN INCLUDE FILE

int PL_get_tail(term_t +l, term_t -t)
    If \( l \) is a list and not [], assign a term-reference to the tail to \( t \).

int PL_get_nil(term_t +l)
    Succeeds if \( t \) represents the atom [].

An example: defining write/1 in C

Figure 9.3 shows a simplified definition of write/1 to illustrate the described functions. This simplified version does not deal with operators. It is called display/1, because it mimics closely the behaviour of this Edinburgh predicate.

9.6.4 Constructing Terms

Terms can be constructed using functions from the PL_put_*() and PL_cons_*() families. This approach builds the term ‘inside-out’, starting at the leaves and subsequently creating compound terms. Alternatively, terms may be created ‘top-down’, first creating a compound holding only variables and subsequently unifying the arguments. This section discusses functions for the first approach. This approach is generally used for creating arguments for PL_call() and PL_open_query.

void PL_put_variable(term_t -t)
    Put a fresh variable in the term. The new variable lives on the global stack. Note that the initial variable lives on the local stack and is lost after a write to the term-references. After using this function, the variable will continue to live.

void PL_put_atom(term_t -t, atom_t a)
    Put an atom in the term reference from a handle. See also PL_new_atom() and PL_atom_chars().

void PL_put_atom_chars(term_t -t, const char *chars)
    Put an atom in the term-reference constructed from the 0-terminated string. The string itself will never be referenced by Prolog after this function.

void PL_put_string_chars(term_t -t, const char *chars)
    Put a zero-terminated string in the term-reference. The data will be copied. See also PL_put_string_nchars().

void PL_put_string_nchars(term_t -t, size_t len, const char *chars)
    Put a string, represented by a length/start pointer pair in the term-reference. The data will be copied. This interface can deal with 0-bytes in the string. See also section 9.6.19.

void PL_put_list_chars(term_t -t, const char *chars)
    Put a list of ASCII values in the term-reference.

void PL_put_integer(term_t -t, long i)
    Put a Prolog integer in the term reference.

void PL_put_int64(term_t -t, int64_t i)
    Put a Prolog integer in the term reference.
foreign_t
pl_display(term_t t)
{
  functor_t functor;
  int arity, len, n;
  char *s;

  switch( PL_term_type(t) )
  { case PL_VARIABLE:
    case PL_ATOM:
    case PL_INTEGER:
    case PL_FLOAT:
      PL_get_chars(t, &s, CVT_ALL);
      Sprintf("%s", s);
      break;
    case PL_STRING:
      PL_get_string_chars(t, &s, &len);
      Sprintf(""\%s\"", s);
      break;
    case PL_TERM:
      { term_t a = PL_new_term_ref();

        PL_get_name arity(t, &name, &arity);
        Sprintf("%s", PL_atom_chars(name));
        for(n=1; n<=arity; n++)
          { PL_get_arg(n, t, a);
            if ( n > 1 )
              Sprintf(" ", );
            pl_display(a);
          }
        Sprintf("");
        break;
      default:                  /* should not happen */
        PL_fail;
    }
  }
  PL_succeed;
}
9.6. THE FOREIGN INCLUDE FILE

void PL_put_pointer(term t -t, void *ptr)
Put a Prolog integer in the term-reference. Provided ptr is in the ‘malloc()-area’, PL_get_pointer() will get the pointer back.

void PL_put_float(term t -t, double f)
Put a floating-point value in the term-reference.

void PL_put_functor(term t -t, functor t functor)
Create a new compound term from functor and bind t to this term. All arguments of the term will be variables. To create a term with instantiated arguments, either instantiate the arguments using the PL_unify_*() functions or use PL_cons functor().

void PL_put_list(term t -l)
Same as PL_put_functor(l, PL_new_functor(PL_new_atom("."), 2)).

void PL_put_nil(term t -l)
Same as PL_put_atom_chars("[]").

void PL_put_term(term t -tl, term t +t2)
Make tl point to the same term as t2.

void PL_cons_functor(term t -h, functor t f, ...)
Create a term, whose arguments are filled from variable argument list holding the same number of term t objects as the arity of the functor. To create the term animal(gnu, 50), use:

{ term_t a1 = PL_new_term_ref();
  term_t a2 = PL_new_term_ref();
  term_t t = PL_new_term_ref();
  functor_t animal2;

  /* animal2 is a constant that may be bound to a global variable and re-used */
  animal2 = PL_new_functor(PL_new_atom("animal"), 2);

  PL_put_atom_chars(a1, "gnu");
  PL_put_integer(a2, 50);
  PL_cons_functor(t, animal2, a1, a2);
}

After this sequence, the term-references a1 and a2 may be used for other purposes.

void PL_cons_functor_v(term t -h, functor t f, term t a0)
Creates a compound term like PL_cons functor(), but a0 is an array of term references as returned by PL_new_term_refs(). The length of this array should match the number of arguments required by the functor.

void PL_cons_list(term t -l, term t +h, term t +t)
Create a list (cons-) cell in l from the head and tail. The code below creates a list of atoms from a char **. The list is built tail-to-head. The PL_unify_*() functions can be used to build a list head-to-tail.
void
put_list(term_t l, int n, char **words)
{
    term_t a = PL_new_term_ref();

    PL_put_nil(l);
    while( --n >= 0 )
    {
        PL_put_atom_chars(a, words[n]);
        PL_cons_list(l, a, l);
    }
}

Note that l can be redefined within a PL_cons_list call as shown here because operationally its old value is consumed before its new value is set.

9.6.5 Unifying data

The functions of this sections unify terms with other terms or translated C-data structures. Except for PL_unify(), the functions of this section are specific to SWI-Prolog. They have been introduced to make translation of old code easier, but also because they provide for a faster mechanism for returning data to Prolog that requires less term-references. Consider the case where we want a foreign function to return the host name of the machine Prolog is running on. Using the PL_get_*() and PL_put_*() functions, the code becomes:

foreign_t
pl_hostname(term_t name)
{
    char buf[100];

    if ( gethostname(buf, sizeof(buf)) )
    {
        term_t tmp = PL_new_term_ref();

        PL_put_atom_chars(tmp, buf);
        return PL_unify(name, tmp);
    }

    PL_fail;
}

Using PL_unify_atom_chars(), this becomes:

foreign_t
pl_hostname(term_t name)
{
    char buf[100];

    if ( gethostname(buf, sizeof(buf)) )
        return PL_unify_atom_chars(name, buf);

    PL_fail;
}
9.6. THE FOREIGN INCLUDE FILE

int PL_unify(term_t ?t1, term_t ?t2)
    Unify two Prolog terms and return non-zero on success.

int PL_unify_atom(term_t ?t, atom_t a)
    Unify t with the atom a and return non-zero on success.

int PL_unify_chars(term_t ?t, int flags, size_t len, const char *chars)
    New function to deal with unification of char* with various encodings to a Prolog representation. The flags argument is a bitwise or specifying the Prolog target type and the encoding of chars. Prolog types is one of PL_ATOM, PL_STRING, PL_CODE_LIST or PL_CHAR_LIST. Representations is one of REP_ISO_LATIN_1, REP_UTF8 or REP_MB. See PL_get_chars() for a definition of the representation types. If len is -1 chars must be 0-terminated and the length is computed from chars using strlen().

    If flags includes PLDIFF_LIST and type is one of PL_CODE_LIST or PL_CHAR_LIST, the text is converted to a difference list. The tail of the difference list is t + 1.

int PL_unify_atom_chars(term_t ?t, const char *chars)
    Unify t with an atom created from chars and return non-zero on success.

int PL_unify_list_chars(term_t ?t, const char *chars)
    Unify t with a list of ASCII characters constructed from chars.

void PL_unify_string_chars(term_t ?t, const char *chars)
    Unify t with a Prolog string object created from the zero-terminated string chars. The data will be copied. See also PL_unify_string_nchars().

void PL_unify_string_nchars(term_t ?t, size_t len, const char *chars)
    Unify t with a Prolog string object created from the string created from the len/chars pair. The data will be copied. This interface can deal with 0-bytes in the string. See also section 9.6.19.

int PL_unify_integer(term_t ?t, long n)
    Unify t with a Prolog integer from n.

int PL_unify_int64(term_t ?t, int64_t n)
    Unify t with a Prolog integer from n.

int PL_unify_float(term_t ?t, double f)
    Unify t with a Prolog float from f.

int PL_unify_pointer(term_t ?t, void *ptr)
    Unify t with a Prolog integer describing the pointer. See also PL_put_pointer() and PL_get_pointer().

int PL_unify_functor(term_t ?t, functor_t f)
    If t is a compound term with the given functor, just succeed. If it is unbound, create a term and bind the variable, else fails. Note that this function does not create a term if the argument is already instantiated.

int PL_unify_list(term_t ?l, term_t -h, term_t -t)
    Unify l with a list-cell (, /2). If successful, write a reference to the head of the list to h and a reference to the tail of the list into t. This reference may be used for subsequent calls to
this function. Suppose we want to return a list of atoms from a `char **`. We could use the example described by `PL_put_list()`, followed by a call to `PL_unify()`, or we can use the code below. If the predicate argument is unbound, the difference is minimal (the code based on `PL_put_list()` is probably slightly faster). If the argument is bound, the code below may fail before reaching the end of the word-list, but even if the unification succeeds, this code avoids a duplicate (garbage) list and a deep unification.

```c
foreign_t
pl_get_environ(term_t env)
{
    term_t l = PL_copy_term_ref(env);
    term_t a = PL_new_term_ref();
    extern char **environ;
    char **e;

    for(e = environ; *e; e++)
    {
        if ( !PL_unify_list(l, a, l) ||
            !PL_unify_atom_chars(a, *e) )
            PL_fail;
    }

    return PL_unify_nil(l);
}
```

`int PL_unify_nil(term_t ?l)`

Unify `l` with the atom `[ ]`.

`int PL_unify_arg(int index, term_t ?t, term_t ?a)`

Unifies the `index-th` argument (1-based) of `t` with `a`.

`int PL_unify_term(term_t ?t, ...)`

Unify `t` with a (normally) compound term. The remaining arguments is a sequence of a type identifier, followed by the required arguments. This predicate is an extension to the Quintus and SICStus foreign interface from which the SWI-Prolog foreign interface has been derived, but has proved to be a powerful and comfortable way to create compound terms from C. Due to the vararg packing/unpacking and the required type-switching this interface is slightly slower than using the primitives. Please note that some bad C-compilers have fairly low limits on the number of arguments that may be passed to a function.

Special attention is required when passing numbers. C 'promotes' any integral smaller than `int` to `int`. I.e. the types `char`, `short` and `int` are all passed as `int`. In addition, on most 32-bit platforms `int` and `long` are the same. Up-to version 4.0.5, only `PL_INTEGER` could be specified which was taken from the stack as `long`. Such code fails when passing small integral types on machines where `int` is smaller than `long`. It is advised to use `PL_SHORT`, `PL_INT` or `PL_LONG` as appropriate. Similar, C compilers promote `float` to `double` and therefore `PL_FLOAT` and `PL_DOUBLE` are synonyms.

The type identifiers are:
PL_VARIABLE none
   No op. Used in arguments of PL_FUNCTOR.

PL_BOOL int
   Unify the argument with true or false.

PL_ATOM atom
   Unify the argument with an atom, as in PL_unify_atom().

PL_CHARS const char *
   Unify the argument with an atom, constructed from the C char *, as in PL_unify_atom_chars().

PL_NCHARS size_t, const char *
   Unify the argument with an atom, constructed from length and char* as in PL_unify_atom_nchars().

PL_UTF8_CHARS const char *
   Create an atom from a UTF-8 string.

PL_UTF8_STRING const char *
   Create a packed string object from a UTF-8 string.

PL_MBCHARS const char *
   Create an atom from a multi-byte string in the current locale.

PL_MBCODES const char *
   Create a list of character codes from a multi-byte string in the current locale.

PL_MSTRING const char *
   Create a packed string object from a multi-byte string in the current locale.

PL_NWCHARS size_t, const wchar_t *
   Create an atom from a length and a wide character pointer.

PL_NWCODES size_t, const wchar_t *
   Create a list of character codes from a length and a wide character pointer.

PL_NWSTRING size_t, const wchar_t *
   Create a packed string object from a length and a wide character pointer.

PL_SHORT short
   Unify the argument with an integer, as in PL_unify_integer(). As short is promoted to int, PL_SHORT is a synonym for PL_INT.

PL_INTEGER long
   Unify the argument with an integer, as in PL_unify_integer().

PL_INT int
   Unify the argument with an integer, as in PL_unify_integer().

PL_LONG long
   Unify the argument with an integer, as in PL_unify_integer().

PL_INT64 int64_t
   Unify the argument with a 64-bit integer, as in PL_unify_int64().

PL_INTPTR intptr_t
   Unify the argument with an integer with the same width as a pointer. On most machines this is the same as PL_LONG, but on 64-bit MS-Windows pointers are 64-bit while longs are only 32-bits.
PL_DOUBLE double
Unify the argument with a float, as in PL_unify_float(). Note that, as the argument is passed using the C vararg conventions, a float must be casted to a double explicitly.

PL_FLOAT double
Unify the argument with a float, as in PL_unify_float().

PL_POINTER void *
Unify the argument with a pointer, as in PL_unify_pointer().

PL_STRING const char *
Unify the argument with a string object, as in PL_unify_string_chars().

PL_TERM term_t
Unify a subterm. Note this may the return value of a PL_new_term_ref() call to get access to a variable.

PL_FUNCTOR functor_t, ...
Unify the argument with a compound term. This specification should be followed by exactly as many specifications as the number of arguments of the compound term.

PL_FUNCTOR_CHARS const char *name, int arity, ...
Create a functor from the given name and arity and then behave as PL_FUNCTOR.

PL_LIST int length, ...
Create a list of the indicated length. The following arguments contain the elements of the list.

For example, to unify an argument with the term language(dutch), the following skeleton may be used:

static functor_t FUNCTOR_language1;

static void
init_constants()
{ FUNCTOR_language1 = PL_new_functor(PL_new_atom("language"), 1);
}

foreign_t
pl_get_lang(term_t r)
{ return PL_unify_term(r,
    PL_FUNCTOR, FUNCTOR_language1,
    PL_CHARS, "dutch");
}

install_t
install()
{ PL_register_foreign("get_lang", 1, pl_get_lang, 0);
    init_constants();
}
int PL_chars_to_term(const char *chars, term_t *t)

Parse the string chars and put the resulting Prolog term into \textit{t}. chars may or may not be closed using a Prolog full-stop (i.e., a dot followed by a blank). Returns \texttt{FALSE} if a syntax error was encountered and \texttt{TRUE} after successful completion. In addition to returning \texttt{FALSE}, the exception-term is returned in \texttt{t} on a syntax error. See also \texttt{term_to_atom/2}.

The following example build a goal-term from a string and calls it.

```c
int call_chars(const char *goal)
{
    fid_t fid = PL_open_foreign_frame();
    term_t g = PL_new_term_ref();
    BOOL rval;

    if ( PL_chars_to_term(goal, g) )
        rval = PL_call(goal, NULL);
    else
        rval = FALSE;

    PL_discard_foreign_frame(fid);
    return rval;
}

... call_chars("consult(load)"); ... 
```

\texttt{char * PL_quote(int chr, const char *string)}

Return a quoted version of string. If \texttt{chr} is `'\'`, the result is a quoted atom. If \texttt{chr} is `'"'`, the result is a string. The result string is stored in the same ring of buffers as described with the \texttt{BUF_RING} argument of \texttt{PL_get_chars();}

In the current implementation, the string is surrounded by \texttt{chr} and any occurrence of \texttt{chr} is doubled. In the future the behaviour will depend on the \texttt{character_escapes Prolog} flag.

9.6.6 BLOBS: Using atoms to store arbitrary binary data

SWI-Prolog atoms as well as strings can represent arbitrary binary data of arbitrary length. This facility is attractive for storing foreign data such as images in an atom. An atom is a unique handle to this data and the atom garbage collector is able to destroy atoms that are no longer referenced by the Prolog engine. This property of atoms makes them attractive as a handle to foreign resources, such as Java atoms, Microsoft’s COM objects, etc., providing safe combined garbage collection.

To exploit these features safely and in an organised manner the SWI-Prolog foreign interface allows for creating ‘atoms’ with additional type information. The type is represented by a structure holding C function pointers that tell Prolog how to handle releasing the atom, writing it, sorting it, etc. Two atoms created with different types can represent the same sequence of bytes. Atoms are first ordered on the rank number of the type and then on the result of the \texttt{compare()} function. Rank numbers are assigned when the type is registered.
Defining a BLOB type

The type PL_blob_t represents a structure with the layout displayed above. The structure contains additional fields at the ... for internal bookkeeping as well as future extension.

typedef struct PL_blob_t
{ unsigned long magic;    /* PL_BLOB_MAGIC */
  unsigned long flags;    /* Bitwise or of PL_BLOB_* */
  char * name;            /* name of the type */
  int (*release)(atom_t a);
  int (*compare)(atom_t a, atom_t b);
  int (*write)(iostream *s, atom_t a, int flags);
  int (*acquire)(atom_t a);
  ...
} PL_blob_t;

For each type exactly one such structure should be allocated. Its first field must be initialised to PL_BLOB_MAGIC. The flags is a bitwise or of the following constants:

**PL_BLOB_TEXT**
If specified the blob is assumed to contain text and is considered a normal Prolog atom.

**PL_BLOB_UNIQUE**
If specified the system ensures that the blob-handle is a unique reference for a blob with the given type, length and content. If this flag is not specified each lookup creates a new blob.

**PL_BLOB_NOCOPY**
By default the content of the blob is copied. Using this flag the blob references the external data directly. The user must ensure the provided pointer is valid as long as the atom lives. If PL_BLOB_UNIQUE is also specified uniqueness is determined by comparing the pointer rather than the data pointed at.

The name field represents the type name as available to Prolog. See also current_blob/2. The other field are function pointers that must be initialised to proper functions or NULL to get the default behaviour of built-in atoms. Below are the defined member functions:

void acquire(atom_t a)
Called if a new blob of this type is created through PL_put_blob() or PL_unify_blob(). This callback may be used together with the release hook to deal with reference counted external objects.

int release(atom_t a)
The blob (atom) a is about to be released. This function can retrieve the data of the blob using PL_blob_data(). If it returns FALSE the atom garbage collector will not reclaim the atom.

int compare(atom_t a, atom_t b)
Compare the blobs a and b, both of which are of the type associated to this blob-type. Return values are, as memcmp(), < 0 if a is less then b, = 0 if both are equal and > 0 otherwise.
9.6. THE FOREIGN INCLUDE FILE

int write(Iostream *s, atom_t a, int flags)
Write the content of the blob a to the stream s and respecting the flags. The flags are a bitwise or of zero or more of the PL_WRT_* flags defined in SWI-Prolog.h. This prototype is available if the undocumented SWI-Stream.h is included before SWI-Prolog.h.

If this function is not provided, write/1 emits the content of the blob for blobs of type PL_BLOB_TEXT or a string of the format <#hex data> for binary blobs.

If a blob type is registered from a loadable object (shared object or DLL) the blob-type must be deregistered before the object may be released.

int PL_unregister_blob_type(PL_blob_t *type)
Unlink the blob type from the registered type and transform the type of possible living blobs to unregistered, avoiding further reference to the type structure, functions referred by it as well as the data. This function returns TRUE if no blobs of this type existed and FALSE otherwise. PL_unregister_blob_type() is intended for the uninstall() hook of foreign modules, avoiding further references to the module.

Accessing blobs
The blob access functions are similar to the atom accessing functions. Blobs being atoms, the atom functions operate on blobs and visa versa. For clarity and possible future compatibility issues however it is not advised to rely on this.

int PL_is_blob(term_t t, PL_blob_t **type)
Succeeds if t refers to a blob, in which case type is filled with the type of the blob.

int PL_unify_blob(term_t t, void *blob, size_t len, PL_blob_t *type)
Unify t to a new blob constructed from the given data and associated to the given type. See also PL_unify_atom_nchars().

int PL_put_blob(term_t t, void *blob, size_t len, PL_blob_t *type)
Store the described blob in t. The return value indicates whether a new blob was allocated (FALSE) or the blob is a reference to an existing blob (TRUE). Reporting new/existing can be used to deal with external objects having their own reference counts. If the return is TRUE this reference count must be incremented and it must be decremented on blob destruction callback. See also PL_put_atom_nchars().

int PL_get_blob(term_t t, void **blob, size_t *len, PL_blob_t **type)
If t holds a blob or atom get the data and type and return TRUE. Otherwise return FALSE. Each result pointer may be NULL, in which case the requested information is ignored.

void * PL_blob_data(atom_t a, size_t *len, PL_blob_t **type)
Get the data and type associated to a blob. This function is mainly used from the callback functions described in section 9.6.6.

9.6.7 Exchanging GMP numbers
If SWI-Prolog is linked with the GNU Multiple Precision Arithmetic Library (GMP, used by default), the foreign interface provides functions for exchanging numeric values to GMP types. To access these
functions the header <gmp.h> must be included before <SWI-Prolog.h>. Foreign code using GMP linked to SWI-Prolog asks for some considerations.

- SWI-Prolog normally rebinds the GMP allocation functions using mp_set_memory_functions(). This means SWI-Prolog must be initialised before the foreign code touches any GMP function. You can call PL_action(PL_GMP_SET_ALLOC_FUNCTIONS, TRUE) to force Prolog’s GMP initialization without doing the rest of the Prolog initialization. If you do not want Prolog rebinding the GMP allocation, call PL_action(PL_GMP_SET_ALLOC_FUNCTIONS, FALSE) before initializing Prolog.

- On Windows, each DLL has its own memory pool. To make exchange of GMP numbers between Prolog and foreign code possible you must either let Prolog rebind the allocation functions (default) or you must recompile SWI-Prolog to link to a DLL version of the GMP library.

Here is an example exploiting the function mpz_nextprime():

```c
#include <gmp.h>
#include <SWI-Prolog.h>

static foreign_t
next_prime(term_t n, term_t prime)
{
    mpz_t mpz;
    int rc;

    mpz_init(mpz);
    if ( PL_get_mpz(n, mpz) )
    {
        mpz_nextprime(mpz, mpz);
        rc = PL_unify_mpz(prime, mpz);
    } else
        rc = FALSE;

    mpz_clear(mpz);
    return rc;
}

install_t
install()
{
    PL_register_foreign("next_prime", 2, next_prime, 0);
}

int PL_get_mpz(term_t t, mpz_t mpz)

    If t represents an integer mpz is filled with the value and the function returns TRUE. Otherwise mpz is untouched and the function returns FALSE. Note that mpz must have been initialised before calling this function and must be cleared using mpz_clear() to reclaim any storage associated with it.
```
9.6.6. THE FOREIGN INCLUDE FILE

int PL_get_mpq(term_t t, mpq_t mpq)
    If t is an integer or rational number (term rdiv/2) mpq is filled with the normalise rational number and the function returns TRUE. Otherwise mpq is untouched and the function returns FALSE. Note that mpq must have been initialised before calling this function and must be cleared using mpq_clear() to reclaim any storage associated with it.

int PL_unify_mpz(term_t t, mpz_t mpz)
    Unify t with the integer value represented by mpz and return TRUE on success. The mpz argument is not changed.

int PL_unify_mpq(term_t t, mpq_t mpq)
    Unify t with a rational number represented by mpq and return TRUE on success. Note that t is unified with an integer if the denominator is 1. The mpq argument is not changed.

9.6.8 Calling Prolog from C

The Prolog engine can be called from C. There are two interfaces for this. For the first, a term is created that could be used as an argument to call/1 and next PL_call() is used to call Prolog. This system is simple, but does not allow to inspect the different answers to a non-deterministic goal and is relatively slow as the runtime system needs to find the predicate. The other interface is based on PL_open_query(), PL_next_solution() and PL_cut_query() or PL_close_query(). This mechanism is more powerful, but also more complicated to use.

Predicate references

This section discusses the functions used to communicate about predicates. Though a Prolog predicate may defined or not, redefined, etc., a Prolog predicate has a handle that is not destroyed, nor moved. This handle is known by the type predicate_t.

predicate_t PL_pred(functor_t f, module_t m)
    Return a handle to a predicate for the specified name/arity in the given module. This function always succeeds, creating a handle for an undefined predicate if no handle was available. If the module argument m is NULL, the current context module is used.

predicate_t PL_predicate(const char *name, int arity, const char* module)
    Same a PL_pred(), but provides a more convenient interface to the C-programmer.

void PL_predicate_info(predicate_t p, atom_t *n, int *a, module_t *m)
    Return information on the predicate p. The name is stored over n, the arity over a, while m receives the definition module. Note that the latter need not be the same as specified with PL_predicate(). If the predicate is imported into the module given to PL_predicate(), this function will return the module where the predicate is defined.

Initiating a query from C

This section discusses the functions for creating and manipulating queries from C. Note that a foreign context can have at most one active query. This implies it is allowed to make strictly nested calls between C and Prolog (Prolog calls C, calls Prolog, calls C, etc., but it is not allowed to open multiple queries and start generating solutions for each of them by calling PL_next_solution(). Be sure to call
PL_cut_query() or PL_close_query() on any query you opened before opening the next or returning control back to Prolog.

qid_t **PL_open_query**(module_t ctx, int flags, predicate_t p, term_t +t0)

Opens a query and returns an identifier for it. This function always succeeds, regardless whether the predicate is defined or not. *ctx* is the context module of the goal. When NULL, the context module of the calling context will be used, or user if there is no calling context (as may happen in embedded systems). Note that the context module only matters for module_transparent predicates. See context_module/1 and module_transparent/1. The *p* argument specifies the predicate, and should be the result of a call to PL_pred() or PL_predicate(). Note that it is allowed to store this handle as global data and reuse it for future queries. The term-reference *t0* is the first of a vector of term-references as returned by PL_new_term_refs(n).

The *flags* arguments provides some additional options concerning debugging and exception handling. It is a bitwise or of the following values:

**PL_Q_NORMAL**

Normal operation. The debugger inherits its settings from the environment. If an exception occurs that is not handled in Prolog, a message is printed and the tracer is started to debug the error.\(^3\)

**PL_Q_NODEBUG**

Switch off the debugger while executing the goal. This option is used by many calls to hook-predicates to avoid tracing the hooks. An example is print/1 calling portray/1 from foreign code.

**PL_Q_CATCH_EXCEPTION**

If an exception is raised while executing the goal, do not report it, but make it available for PL_exception().

**PL_Q_PASS_EXCEPTION**

As **PL_Q_CATCH_EXCEPTION**, but do not invalidate the exception-term while calling PL_close_query(). This option is experimental.

The example below opens a query to the predicate is_a/2 to find the ancestor of for some name.

```c
char *
ancestor(const char *me)
{ term_t a0 = PL_new_term_refs(2);
  static predicate_t p;

  if ( !p )
    p = PL_predicate("is_a", 2, "database");

  PL_put_atom_chars(a0, me);
  PL_open_query(NULL, PL_Q_NORMAL, p, a0);
  ...
}
```

\(^3\)Do not pass the integer 0 for normal operation, as this is interpreted as **PL_Q_NODEBUG** for backward compatibility reasons.
9.6. THE FOREIGN INCLUDE FILE

int PL_next_solution(qid, qid)
   Generate the first (next) solution for the given query. The return value is TRUE if a solution
   was found, or FALSE to indicate the query could not be proven. This function may be called
   repeatedly until it fails to generate all solutions to the query.

void PL_cut_query(qid)
   Discards the query, but does not delete any of the data created by the query. It just invalidate
   qid, allowing for a new call to PL_open_query() in this context.

void PL_close_query(qid)
   As PL_cut_query(), but all data and bindings created by the query are destroyed.

int PL_call_predicate(module_t m, int flags, predicate_t pred, term_t +t0)
   Shorthand for PL_open_query(), PL_next_solution(), PL_cut_query(), generating a single so-
   lution. The arguments are the same as for PL_open_query(), the return value is the same as
   PL_next_solution().

int PL_call(term_t, module_t)
   Call term just like the Prolog predicate once/1. Term is called in the specified module, or in
   the context module if module_t = NULL. Returns TRUE if the call succeeds, FALSE otherwise.
   Figure 9.4 shows an example to obtain the number of defined atoms. All checks are omitted to
   improve readability.

9.6.9 Discarding Data

The Prolog data created and term-references needed to setup the call and/or analyse the result can in
most cases be discarded right after the call. PL_close_query() allows for destructing the data, while
leaving the term-references. The calls below may be used to destroy term-references and data. See
figure 9.4 for an example.

fid_t PL_open_foreign_frame()
   Created a foreign frame, holding a mark that allows the system to undo bindings and destroy
   data created after it as well as providing the environment for creating term-references. This
   function is called by the kernel before calling a foreign predicate.

void PL_close_foreign_frame(fid_t id)
   Discard all term-references created after the frame was opened. All other Prolog data is re-
   tained. This function is called by the kernel whenever a foreign function returns control back
   to Prolog.

void PL_discard_foreign_frame(fid_t id)
   Same as PL_close_foreign_frame(), but also undo all bindings made since the open and destroy
   all Prolog data.

void PL_rewind_foreign_frame(fid_t id)
   Undo all bindings and discard all term-references created since the frame was created, but does
   not pop the frame. I.e. the same frame can be rewinded multiple times, and must eventually be
   closed or discarded.

   It is obligatory to call either of the two closing functions to discard a foreign frame. Foreign
   frames may be nested.
int count_atoms() {
  fid_t fid = PL_open_foreign_frame();
  term_t goal = PL_new_term_ref();
  term_t a1 = PL_new_term_ref();
  term_t a2 = PL_new_term_ref();
  functor_t s2 = PL_new_functor(PL_new_atom("statistics"), 2);
  int atoms;

  PL_put_atom_chars(a1, "atoms");
  PL_cons_functor(goal, s2, a1, a2);
  PL_call(goal, NULL); /* call it in current module */

  PL_get_integer(a2, &atoms);
  PL_discard_foreign_frame(fid);

  return atoms;
}

Figure 9.4: Calling Prolog

9.6.10 Foreign Code and Modules

Modules are identified via a unique handle. The following functions are available to query and manipulate modules.

module_t PL_context()
  Return the module identifier of the context module of the currently active foreign predicate.

int PL_strip_module(term_t +raw, module_t *m, term_t -plain)
  Utility function. If raw is a term, possibly holding the module construct ⟨module⟩:⟨rest⟩ this function will make plain a reference to ⟨rest⟩ and fill module * with ⟨module⟩. For further nested module constructs the inner most module is returned via module *. If raw is not a module construct arg will simply be put in plain. If module * is NULL it will be set to the context module. Otherwise it will be left untouched. The following example shows how to obtain the plain term and module if the default module is the user module:

  { module m = PL_new_module(PL_new_atom("user"));
    term_t plain = PL_new_term_ref();
    
    PL_strip_module(term, &m, plain);
    ...

atom_t PL_module_name(module_t m)
  Return the name of module as an atom.

module_t PL_new_module(atom_t name)
  Find an existing or create a new module with name specified by the atom name.
9.6.11 Prolog exceptions in foreign code

This section discusses PL_exception(), PL_throw() and PL_raise_exception(), the interface functions to detect and generate Prolog exceptions from C-code. PL_throw() and PL_raise_exception() from the C-interface to raise an exception from foreign code. PL_throw() exploits the C-function longjmp() to return immediately to the innermost PL_next_solution(). PL_raise_exception() registers the exception term and returns FALSE. If a foreign predicate returns FALSE, while an exception-term is registered a Prolog exception will be raised by the virtual machine.

Calling these functions outside the context of a function implementing a foreign predicate results in undefined behaviour.

PL_exception() may be used after a call to PL_next_solution() fails, and returns a term reference to an exception term if an exception was raised, and 0 otherwise.

If a C-function, implementing a predicate calls Prolog and detects an exception using PL_exception(), it can handle this exception, or return with the exception. Some caution is required though. It is not allowed to call PL_close_query() or PL_discard_foreign_frame() afterwards, as this will invalidate the exception term. Below is the code that calls a Prolog defined arithmetic function (see arithmetic_function/1).

If PL_next_solution() succeeds, the result is analysed and translated to a number, after which the query is closed and all Prolog data created after PL_open_foreign_frame() is destroyed. On the other hand, if PL_next_solution() fails and an exception was raised, just pass it. Otherwise generate an exception (PL_error() is an internal call for building the standard error terms and calling PL_raise_exception()). After this, the Prolog environment should be discarded using PL_cut_query() and PL_close_foreign_frame() to avoid invalidating the exception term.

```c
static int prologFunction(ArithFunction f, term_t av, Number r)
{
    int arity = f->proc->definition->functor->arity;
    fid_t fid = PL_open_foreign_frame();
    qid_t qid;
    int rval;

    qid = PL_open_query(NULL, PL_Q_NORMAL, f->proc, av);

    if ( PL_next_solution(qid) )
    {
        rval = valueExpression(av+arity-1, r);
        PL_close_query(qid);
        PL_discard_foreign_frame(fid);
    } else
    {
        term_t except;
        if ( (except = PL_exception(qid)) )
        {
            rval = PL_throw(except); /* pass exception */
        } else
        {
            char *name = stringAtom(f->proc->definition->functor->name);
            /* generate exception */
            rval = PL_error(name, arity-1, NULL, ERR_FAILED, f->proc);
        }
    }
}
```
int **PL_raise_exception(term_t exception)**

Generate an exception (as throw/1) and return FALSE. Below is an example returning an exception from foreign predicate:

```c

foreign_t
pl_hello(term_t to)
{
    char *s;

    if ( PL_get_atom_chars(to, &s) )
        { printf("Hello \"%s\"\n", s);
            PL_succeed;
        } else
        { term_t except = PL_new_term_ref();
            PL_unify_term(except,
                PL_FUNCTOR_CHARS, "type_error", 2,
                PL_CHARS, "atom",
                PL_TERM, to);
            return PL_raise_exception(except);
        }
}
```

int **PL.throw(term_t exception)**

Similar to PL_raise_exception(), but returns using the C longjmp() function to the innermost PL_next_solution().

**term_t **PL.exception(qid_t qid)**

If PL_next_solution() fails, this can be due to normal failure of the Prolog call, or because an exception was raised using throw/1. This function returns a handle to the exception term if an exception was raised, or 0 if the Prolog goal simply failed. \(^4\)

\(^4\)This interface differs in two ways from Quintus. The calling predicates simply signal failure if an exception was raised, and a term referenced is returned, rather passed and filled with the error term. Exceptions can only be handled using the PL_next_solution() interface, as a handle to the query is required.
9.6.12 Catching Signals (Software Interrupts)

SWI-Prolog offers both a C and Prolog interface to deal with software interrupts (signals). The Prolog mapping is defined in section 4.10. This subsection deals with handling signals from C.

If a signal is not used by Prolog and the handler does not call Prolog in any way, the native signal interface routines may be used.

Some versions of SWI-Prolog, notably running on popular Unix platforms, handle SIGSEGV for guarding the Prolog stacks. If the application wishes to handle this signal too, it should use PL_signal() to install its handler after initialising Prolog. SWI-Prolog will pass SIGSEGV to the user code if it detected the signal is not related to a Prolog stack overflow.

Any handler that wishes to call one of the Prolog interface functions should call PL_signal() for its installation.

```c
void (*)() PL_signal(sig, func)
```

This function is equivalent to the BSD-Unix signal() function, regardless of the platform used. The signal handler is blocked while the signal routine is active, and automatically reactivated after the handler returns.

After a signal handler is registered using this function, the native signal interface redirects the signal to a generic signal handler inside SWI-Prolog. This generic handler validates the environment, creates a suitable environment for calling the interface functions described in this chapter and finally calls the registered user-handler.

By default, signals are handled asynchronously (i.e. at the time they arrive). It is inherently dangerous to call extensive code fragments, and especially exception related code from asynchronous handlers. The interface allows for synchronous handling of signals. In this case the native OS handler just schedules the signal using PL_raise(), which is checked by PL_handle_signals() at the call- and redo-port. This behaviour is realised by or-ing sig with the constant PL_SIGSYNC.5

Signal handling routines may raise exceptions using PL_raise_exception(). The use of PL_throw() is not safe. If a synchronous handler raises an exception, the exception is delayed to the next call to PL_handle_signals();

```c
int PL_raise(int sig)
```

Register sig for synchronous handling by Prolog. Synchronous signals are handled at the call-port or if foreign code calls PL_handle_signals(). See also thread_signal/2.

```c
int PL_handle_signals(void)
```

Handle any signals pending from PL_raise(). PL_handle_signals() is called at each pass through the call- and redo-port at a safe point. Exceptions raised by the handler using PL_raise_exception() are properly passed to the environment.

The user may call this function inside long-running foreign functions to handle scheduled interrupts. This routine returns the number of signals handled. If a handler raises an exception, the return value is -1 and the calling routine should return with FALSE as soon as possible.

```c
int PL_get_signum_ex(term J t, int *sig)
```

Extract a signal specification from a Prolog term and store as integer signal number in sig. The specification is an integer, lowercase signal name without SIG or the full signal name. These

---

5 A better default would be to use synchronous handling, but this interface preserves backward compatibility.
refer to the same: \texttt{9,kill} and \texttt{SIGKILL}. Leaves a typed, domain or instantiation error if the conversion fails.

9.6.13 Miscellaneous

Term Comparison

\begin{verbatim}
int \texttt{PL\_compare(term\_t t1, term\_t t2)}
\end{verbatim}

Compares two terms using the standard order of terms and returns -1, 0 or 1. See also \texttt{compare/3}.

\begin{verbatim}
int \texttt{PL\_same\_compound(term\_t t1, term\_t t2)}
\end{verbatim}

Yields \texttt{TRUE} if \texttt{t1} and \texttt{t2} refer to physically the same compound term and \texttt{FALSE} otherwise.

Recorded database

In some applications it is useful to store and retrieve Prolog terms from C-code. For example, the XPCE graphical environment does this for storing arbitrary Prolog data as slot-data of XPCE objects.

Please note that the returned handles have no meaning at the Prolog level and the recorded terms are not visible from Prolog. The functions \texttt{PL\_recorded()} and \texttt{PL\_erase()} are the only functions that can operate on the stored term.

Two groups of functions are provided. The first group (\texttt{PL\_record()} and friends) store Prolog terms on the Prolog heap for retrieval during the same session. These functions are also used by \texttt{recorda/3} and friends. The recorded database may be used to communicate Prolog terms between threads.

\begin{verbatim}
record\_t \texttt{PL\_record(term\_t t)}
\end{verbatim}

Record the term \texttt{t} into the Prolog database as \texttt{recorda/3} and return an opaque handle to the term. The returned handle remains valid until \texttt{PL\_erase()} is called on it. \texttt{PL\_recorded()} is used to copy recorded terms back to the Prolog stack.

\begin{verbatim}
void \texttt{PL\_recorded(record\_t record, term\_t t)}
\end{verbatim}

Copy a recorded term back to the Prolog stack. The same record may be used to copy multiple instances at any time to the Prolog stack. See also \texttt{PL\_record()} and \texttt{PL\_erase()}.

\begin{verbatim}
void \texttt{PL\_erase(record\_t record)}
\end{verbatim}

Remove the recorded term from the Prolog database, reclaiming all associated memory resources.

The second group (headed by \texttt{PL\_record\_external()}) provides the same functionality, but the returned data has properties that enable storing the data on an external device. It has been designed to make it possible to store Prolog terms fast an compact in an external database. Here are the main features:

- \textit{Independent of session}

Records can be communicated to another Prolog session and made visible using \texttt{PL\_recorded\_external()}.

- \textit{Binary}

The representation is binary for maximum performance. The returned data may contain 0-bytes.
9.6. THE FOREIGN INCLUDE FILE

- **Byte-order independent**
  The representation can be transferred between machines with different byte-order.

- **No alignment restrictions**
  There are no memory alignment restrictions and copies of the record can thus be moved freely. For example, it is possible to use this representation to exchange terms using shared memory between different Prolog processes.

- **Compact**
  It is assumed that a smaller memory footprint will eventually outperform slightly faster representations.

- **Stable**
  The format is designed for future enhancements without breaking compatibility with older records.

```c
char * PL_record_external(term *t, size_t *len)
```

Record the term \( t \) into the Prolog database as `recorda/3` and return an opaque handle to the term. The returned handle remains valid until `PL_erase_external()` is called on it.

It is allowed to copy the data and use `PL_recorded_external()` on the copy. The user is responsible for the memory management of the copy. After copying, the original may be discarded using `PL_erase_external()`.

`PL_recorded_external()` is used to copy such recorded terms back to the Prolog stack.

```c
int PL_recorded_external(const char *record, term *t)
```

Copy a recorded term back to the Prolog stack. The same record may be used to copy multiple instances at any time to the Prolog stack. See also `PL_record_external()` and `PL_erase_external()`.

```c
int PL_erase_external(char *record)
```

Remove the recorded term from the Prolog database, reclaiming all associated memory resources.

**Getting file names**

The function `PL_get_file_name()` provides access to Prolog filenames and its file-search mechanism described with `absolute_file_name/3`. Its existence is motivated to realise a uniform interface to deal with file-properties, search, naming conventions etc. from foreign code.

```c
int PL_get_file_name(term *spec, char **name, int flags)
```

Translate a Prolog term into a file name. The name is stored in the static buffer ring described with `PL_get_chars()` option `BUF_RING`. Conversion from the internal UNICODE encoding is done using standard C library functions. `flags` is a bit-mask controlling the conversion process. Options are:

- `PL_FILE_ABSOLUTE`
  - Return an absolute path to the requested file.

- `PL_FILE_OSPATH`
  - Return the name using the hosting OS conventions. On MS-Windows, \ is used to separate directories rather than the canonical /.
PL_FILE_SEARCH
   Invoke absolute_file_name/3. This implies rules from file_search.path/2 are used.

PL_FILE_EXIST
   Demand the path to refer to an existing entity.

PL_FILE_READ
   Demand read-access on the result.

PL_FILE_WRITE
   Demand write-access on the result.

PL_FILE_EXECUTE
   Demand execute-access on the result.

PL_FILE_NOERRORS
   Do not raise any exceptions.

9.6.14 Errors and warnings

PL_warning() prints a standard Prolog warning message to the standard error (user.error) stream. Please note that new code should consider using PL_raise_exception() to raise a Prolog exception. See also section 4.9.

int PL_warning(format, a1, ...)
   Print an error message starting with ‘[WARNING: ’, followed by the output from format, followed by a ‘]’ and a newline. Then start the tracer. format and the arguments are the same as for printf(2). Always returns FALSE.

9.6.15 Environment Control from Foreign Code

int PL_action(int, ...)
   Perform some action on the Prolog system. int describes the action, Remaining arguments depend on the requested action. The actions are listed in table 9.1.

9.6.16 Querying Prolog

long PL_query(int)
   Obtain status information on the Prolog system. The actual argument type depends on the information required. int describes what information is wanted.\(^6\) The options are given in table 9.2.

9.6.17 Registering Foreign Predicates

int PL_register_foreign_in_module(const char *module, const char *name, int arity, foreign_t (*function)(), int flags)
   Register a C-function to implement a Prolog predicate. After this call returns successfully a predicate with name name (a char *) and arity arity (a C int) is created in module module. If module is NULL, the predicate is created in the module of the calling context or if no context is present in the module user.

\(^6\)Returning pointers and integers as a long is bad style. The signature of this function should be changed.
<table>
<thead>
<tr>
<th>PL_ACTION_TRACE</th>
<th>Start Prolog tracer (trace/0). Requires no arguments.</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL_ACTION_DEBUG</td>
<td>Switch on Prolog debug mode (debug/0). Requires no arguments.</td>
</tr>
<tr>
<td>PL_ACTION_BACKTRACE</td>
<td>Print backtrace on current output stream. The argument (an int) is the number of frames printed.</td>
</tr>
<tr>
<td>PL_ACTION_HALT</td>
<td>Halt Prolog execution. This action should be called rather than Unix exit() to give Prolog the opportunity to clean up. This call does not return. The argument (an int) is the exit code. See halt/1.</td>
</tr>
<tr>
<td>PL_ACTION_ABORT</td>
<td>Generate a Prolog abort (abort/0). This call does not return. Requires no arguments.</td>

<td>Return the default stream encoding of Prolog (of type IOENC).</td>
</tr>
<tr>
<td>PL_QUERY_USER_CPU</td>
<td>Get amount of user CPU time of the process in milliseconds.</td>
</tr>
</tbody>
</table>

Table 9.2: PL_query() options

When called in Prolog, Prolog will call function. flags forms bitwise or’ed list of options for the installation. These are:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PL_FA_NOTRACE</td>
<td>Predicate cannot be seen in the tracer</td>
</tr>
<tr>
<td>PL_FA_TRANSPARENT</td>
<td>Predicate is module transparent</td>
</tr>
<tr>
<td>PL_FA_NONDETERMINISTIC</td>
<td>Predicate is non-deterministic. See also PL_retry().</td>
</tr>
<tr>
<td>PL_FA_VARARGS</td>
<td>Use alternative calling convention.</td>
</tr>
</tbody>
</table>

Predicates may be registered either before or after PL_initialise(). When registered before initialisation the registration is recorded and executed after installing the system predicates and before loading the saved state.

Default calling (i.e. without PL_FA_VARARGS) function is passed the same number of term_t arguments as the arity of the predicate and, if the predicate is non-deterministic, an extra argument of type control_t (see section 9.6.1). If PL_FA_VARARGS is provided, function is called with three arguments. The first argument is a term_t handle to the first argument. Further arguments can be reached by adding the offset (see also PL_new_termRefs()). The second argument is the arity, which defines the number of valid term-references in the argument vector. The last argument is used for non-deterministic calls. It is currently undocumented and should be defined of type void*. Here is an example:

```c
static foreign_t
atom_checksum(term_t a0, int arity, void* context)
{ char *s;
```
if ( PL_get_atom_chars(a0, &s) )
{
    int sum;

    for(sum=0; *s; s++)
        sum += *s&0xff;

    return PL_unify_integer(a0+1, sum&0xff);
}

return FALSE;

install_t
install()
{
    PL_register_foreign("atom_checksum", 2, atom_checksum, PL_FA_VARARGS);
}

int PL_register_foreign(const char *name, int arity, foreign_t (*function)(), int flags)
Same as PL_register_foreign_in_module(), passing NULL for the module.

void PL_register_extensions_in_module(const char *module, PL_extension *e)
Register a series of predicates from an array of definitions of the type PL_extension in the
given module. If module is NULL, the predicate is created in the module of the calling context
or if no context is present in the module user. The PL_extension type is defined as

typedef struct PL_extension
{
    char     *predicate_name; /* Name of the predicate */
    short    arity; /* Arity of the predicate */
    pl_function_t function; /* Implementing functions */
    short    flags; /* Or of PL_FA_... */
} PL_extension;

For details, see PL_register_foreign_in_module(). Here is an example of its usage:

static PL_extension predicates[] = {
    { "foo", 1, pl_foo, 0 },
    { "bar", 2, pl_bar, PL_FA_NONDETERMINISTIC },
    { NULL, 0, NULL, 0 }
};

main(int argc, char **argv)
{
    PL_register_extensions_in_module("user", predicates);

    if ( !PL_initialise(argc, argv) )
        PL_halt(1);
void PL_register_extensions( PL_extension *e)
    Same as PL_register_extensions_in_module() using NULL for the module argument.

9.6.18 Foreign Code Hooks

For various specific applications some hooks are provided.

PL_dispatch_hook_t PL_dispatch_hook(PL_dispatch_hook_t)
    If this hook is not NULL, this function is called when reading from the terminal. It is supposed
to dispatch events when SWI-Prolog is connected to a window environment. It can return
two values: PL_DISPATCH_INPUT indicates Prolog input is available on file descriptor 0
or PL_DISPATCH_TIMEOUT to indicate a timeout. The old hook is returned. The type
PL_dispatch_hook_t is defined as:

    typedef int (*PL_dispatch_hook_t)(void);

void PL_abort_hook(PL_abort_hook_t)
    Install a hook when abort/0 is executed. SWI-Prolog abort/0 is implemented using C
setjmp()/longjmp() construct. The hooks are executed in the reverse order of their registration
after the longjmp() took place and before the Prolog top-level is reinvoked. The type
PL_abort_hook_t is defined as:

    typedef void (*PL_abort_hook_t)(void);

int PL_abort_unhook(PL_abort_hook_t)
    Remove a hook installed with PL_abort_hook(). Returns FALSE if no such hook is found,
TRUE otherwise.

void PL_on_halt(void (*)(int, void *), void *closure)
    Register the function f to be called if SWI-Prolog is halted. The function is called with two
arguments: the exit code of the process (0 if this cannot be determined on your operating
system) and the closure argument passed to the PL_on_halt() call. See also at_halt/1.

PL_agc_hook_t PL_agc_hook(PL_agc_hook_t new)
    Register a hook with the atom-garbage collector (see garbage_collect_atoms/0 that is
called on any atom that is reclaimed. The old hook is returned. If no hook is currently defined,
NULL is returned. The argument of the called hook is the atom that is to be garbage collected.
The return value is an int. If the return value is zero, the atom is not reclaimed. The hook
may invoke any Prolog predicate.

The example below defines a foreign library for printing the garbage collected atoms for debugging purposes.
9.6. THE FOREIGN INCLUDE FILE

```c
#include <SWI-Stream.h>
#include <SWI-Prolog.h>

static int
atom_hook(atom_t a)
{ Sdprintf("AGC: deleting %s\n", PL_atom_chars(a));

    return TRUE;
}

static PL_agc_hook_t old;

install_t
install()
{ old = PL_agc_hook(atom_hook);
}

install_t
uninstall()
{ PL_agc_hook(old);
}
```

9.6.19 Storing foreign data

This section provides some hints for handling foreign data in Prolog. With foreign data, we refer to data that is used by foreign language predicates and needs to be passed around in Prolog. Excluding combinations, there are three principal options for storing such data

- **Natural Prolog data**
  E.i. using the representation one would choose if there was no foreign interface required.

- **Opaque packed Prolog data**
  Data can also be represented in a foreign structure and stored on the Prolog stacks using PL_put_string_nchars() and retrieved using PL_get_string_chars(). It is generally good practice to wrap the string in a compound term with arity 1, so Prolog can identify the type. `portray/1` rules may be used to streamline printing such terms during development.

- **Natural foreign data, passing a pointer**
  An alternative is to pass a pointer to the foreign data. Again, this functor may be wrapped in a compound term.

The choice may be guided using the following distinctions

- **Is the data opaque to Prolog**
  With ‘opaque’ data, we refer to data handled in foreign functions, passed around in Prolog, but of which Prolog never examines the contents of the data itself. If the data is opaque to Prolog, the chosen representation does not depend on simple analysis by Prolog, and the selection will be driven solely by simplicity of the interface and performance (both in time and space).

- **How big is the data**
  
  Is efficient encoding required? For example, a boolean array may be expressed as a compound term, holding integers each of which contains a number of bits, or as a list of `true` and `false`.

- **What is the nature of the data**
  
  For examples in C, constants are often expressed using ‘enum’ or `#define’d` integer values. If prolog needs to handle this data, atoms are a more logical choice. Whether or not this mapping is used depends on whether Prolog needs to interpret the data, how important debugging is and how important performance is.

- **What is the lifetime of the data**
  
  We can distinguish three cases.

  1. The lifetime is dictated by the accessibility of the data on the Prolog stacks. Their is no way by which the foreign code when the data becomes ‘garbage’, and the data thus needs to be represented on the Prolog stacks using Prolog data-types. (2).

  2. The data lives on the ‘heap’ and is explicitly allocated and deallocated. In this case, representing the data using native foreign representation and passing a pointer to it is a sensible choice.

  3. The data lives as during the lifetime of a foreign predicate. If the predicate is deterministic, foreign automatic variables are suitable. If the predicate is non-deterministic, the data may be allocated using `malloc()` and a pointer may be passed. See section 9.6.1.

**Examples for storing foreign data**

In this section, we will outline some examples, covering typical cases. In the first example, we will deal with extending Prolog’s data representation with integer-sets, represented as bit-vectors. Finally, we discuss the outline of the DDE interface.

**Integer sets** with not-too-far-apart upper- and lower-bounds can be represented using bit-vectors. Common set operations, such as union, intersection, etc. are reduced to simple and’ing and or’ing the bit-vectors. This can be done using Prolog’s unbounded integers.

For really demanding applications, foreign representation will perform better, especially time-wise. Bit-vectors are naturally expressed using string objects. If the string is wrapped in `bitvector/1`, lower-bound of the vector is 0, and the upper-bound is not defined, an implementation for getting and putting the sets as well as the union predicate for it is below.

```c
#include <SWI-Prolog.h>

#define max(a, b) ((a) > (b) ? (a) : (b))
#define min(a, b) ((a) < (b) ? (a) : (b))

static functor_t FUNCTOR_bitvector1;

static int
get_bitvector(term_t in, int *len, unsigned char **data)
    { if ( PL_is_functor(in, FUNCTOR_bitvector1) )
```
{ term_t a = PL_new_term_ref();

    PL_get_arg(1, in, a);
    return PL_get_string(a, (char **)data, len);
}

PL_fail;
}

static int
unify_bitvector(term_t out, int len, const unsigned char *data)
{ if ( PL_unify_functor(out, FUNCTOR_bitvector1) )
    { term_t a = PL_new_term_ref();

        PL_get_arg(1, out, a);

        return PL_unify_string_nchars(a, len, (const char *)data);
    }

    PL_fail;
}

static foreign_t
pl_bitvector_union(term_t t1, term_t t2, term_t u)
{ unsigned char *s1, *s2;
    int l1, l2;

    if ( get_bitvector(t1, &l1, &s1) &&
        get_bitvector(t2, &l2, &s2) )
    { int l = max(l1, l2);
        unsigned char *s3 = alloca(l);

        if ( s3 )
        { int n;
            int ml = min(l1, l2);

            for(n=0; n<ml; n++)
                s3[n] = s1[n] | s2[n];
            for( ; n < l1; n++)
                s3[n] = s1[n];
            for( ; n < l2; n++)
                s3[n] = s2[n];

            return unify_bitvector(u, l, s3);
        }

        return PL_warning("Not enough memory");
    }
The DDE interface (see section 4.42) represents another common usage of the foreign interface: providing communication to new operating system features. The DDE interface requires knowledge about active DDE server and client channels. These channels contain various foreign data-types. Such an interface is normally achieved using an open/close protocol that creates and destroys a handle. The handle is a reference to a foreign data-structure containing the relevant information.

There are a couple of possibilities for representing the handle. The choice depends on responsibilities and debugging facilities. The simplest approach is to use PL_unify_pointer() and PL_get_pointer(). This approach is fast and easy, but has the drawbacks of (untyped) pointers: there is no reliable way to detect the validity of the pointer, not to verify it is pointing to a structure of the desired type. The pointer may be wrapped into a compound term with arity 1 (i.e., dde_channel(⟨Pointer⟩)), making the type-problem less serious.

Alternatively (used in the DDE interface), the interface code can maintain a (preferably variable length) array of pointers and return the index in this array. This provides better protection. Especially for debugging purposes, wrapping the handle in a compound is a good suggestion.

9.6.20 Embedding SWI-Prolog in other applications

With embedded Prolog we refer to the situation where the ‘main’ program is not the Prolog application. Prolog is sometimes embedded in C, C++, Java or other languages to provide logic based services in a larger application. Embedding loads the Prolog engine as a library to the external language. Prolog itself only provides for embedding in the C-language (compatible to C++). Embedding in Java is achieved using JPL using a C-glue between the Java and Prolog C-interfaces.

The most simple embedded program is below. The interface function PL_initialise() must be called before any of the other SWI-Prolog foreign language functions described in this chapter, except for PL_initialise_hook(), PL_new_atom(), PL_new_functor() and PL_register_foreign(). PL_initialise() interprets all the command-line arguments, except for the -t toplevel flag that is interpreted by PL_toplevel().

```c
int main(int argc, char **argv)
{
    #ifdef READLINE /* Remove if you don’t want readline */
        PL_initialise_hook(install_readline);
    #endif
```
9.6. THE FOREIGN INCLUDE FILE

```c
#endif

if ( !PL_initialise(argc, argv) )
    PL_halt(1);

PL_halt(PL_toplevel() ? 0 : 1);
}

int PL_initialise(int argc, char ***argv)
Initialises the SWI-Prolog heap and stacks, restores the Prolog state, loads the system and
personal initialisation files, runs the at_initialization/1 hooks and finally runs the
-g goal hook.

Special consideration is required for argv[0]. On Unix, this argument passes the part of the
command-line that is used to locate the executable. Prolog uses this to find the file holding the
running executable. The Windows version uses this to find a module of the running executable.
If the specified module cannot be found, it tries the module libpl.dll, containing the Prolog
runtime kernel. In all these cases, the resulting file is used for two purposes

- See whether a Prolog saved-state is appended to the file. If this is the case, this state will
  be loaded instead of the default boot.prc file from the SWI-Prolog home directory. See
  also qsave_program/[1,2] and section 9.7.
- Find the Prolog home directory. This process is described in detail in section 9.8.

PL_initialise() returns 1 if all initialisation succeeded and 0 otherwise.\(^7\)

In most cases, argc and argv will be passed from the main program. It is allowed to create
your own argument vector, provided argv[0] is constructed according to the rules above. For
example:

```c
int main(int argc, char **argv)
{
    char *av[10];
    int ac = 0;

    av[ac++] = argv[0];
    av[ac++] = "-x";
    av[ac++] = "mystate";
    av[ac] = NULL;

    if ( !PL_initialise(ac, av) )
        PL_halt(1);
    ...
}
```

\(^7\)BUG: Various fatal errors may cause PL_initialise to call PL_halt(1), preventing it from returning at all.
Please note that the passed argument vector may be referred from Prolog at any time and should therefore be valid as long as the Prolog engine is used.

A good setup in Windows is to add SWI-Prolog’s bin directory to your PATH and either pass a module holding a saved-state, or "libpl.dll" as argv[0]. If the Prolog state is attached to a DLL (see the -dll option of plld, pass the name of this DLL.

```c
int PL_is_initialised(int *argc, char ***argv)
```

Test whether the Prolog engine is already initialised. Returns FALSE if Prolog is not initialised and TRUE otherwise. If the engine is initialised and argc is not NULL, the argument count used with PL_initialise() is stored in argc. Same for the argument vector argv.

```c
void PL_install_readline()
```

Installs the GNU-readline line-editor. Embedded applications that do not use the Prolog toplevel should normally delete this line, shrinking the Prolog kernel significantly. Note that the Windows version does not use GNU readline.

```c
int PL_toplevel()
```

Runs the goal of the -t toplevel switch (default prolog/0) and returns 1 if successful, 0 otherwise.

```c
void PL_cleanup(int status)
```

This function performs the reverse of PL initialise(). It runs the PL_on_halt() and at_halt/1 handlers, closes all streams (except for the ‘standard I/O’ streams which are flushed only), deallocates all memory and restores all signal handlers. The status argument is passed to the various termination hooks and indicates the exit-status.

This function allows deleting and restarting the Prolog system in the same process. Use it with care, as PL Initialise() is a costly function. Unix users should consider using exec() (available as part of the clib package.).

```c
void PL_cleanup_fork()
```

Close file descriptors associated to Prolog streams except for 0,1 and 2. Stop intervaltimer that may be running on behalf of profile/1. The call is intended to be used in combination with fork():

```c
if ( (pid=fork()) == 0 )
{ PL_cleanup_fork();
  <some exec variation>
}
```

The call behaves the same on Windows, though there is probably no meaningful application.

```c
int PL_halt(int status)
```

Cleanup the Prolog environment using PL_cleanup() and calls exit() with the status argument. As PL_cleanup() can only be called from the main thread, this function returns FALSE when called from another thread as the main one.\(^8\)

\(^8\)Bug: Eventually it may become possible to call PL_halt() from any thread.
Threading, Signals and embedded Prolog

This section applies to Unix-based environments that have signals or multi-threading. The Windows version is compiled for multi-threading and Windows lacks proper signals.

We can distinguish two classes of embedded executables. There are small C/C++-programs that act as an interfacing layer around Prolog. Most of these programs can be replaced using the normal Prolog executable extended with a dynamically loaded foreign extension and in most cases this is the preferred route. In other cases, Prolog is embedded in a complex application that—like Prolog—wants to control the process environment. A good example is Java. Embedding Prolog is generally the only way to get these environments together in one process image. Java applications however are by nature multi-threaded and appear to do signal-handling (software interrupts).

To make Prolog operate smoothly in such environments it must be told not to alter the process environment. This is partly done at build-time and partly execution time. At build-time we must specify the use of software stack-overflow rather then the default hardware checks. This is done using

```
sh configure --disable-segv-handling
```

The resulting Prolog executable is about 10% slower than the normal executable, but behaves much more reliable in complicated embedded situations. In addition, as the process no longer handles segmentation violations, debugging foreign code linked to it is much easier.

At runtime, it is advised to pass the flag `-nosignals`, which inhibits all default signal handling. This has a few consequences though:

- It is no longer possible to break into the tracer using an interrupt signal (Control-C).
- `SIGPIPE` is normally set to be ignored. Prolog uses return-codes to diagnose broken pipes. Depending on the situation one should take appropriate action if Prolog streams are connected to pipes.
- Fatal errors normally cause Prolog to call PL\_cleanup() and exit(). It is advised to call PL\_cleanup() as part of the exit-procedure of your application.

9.7 Linking embedded applications using plld

The utility program plld (Win32: plld.exe) may be used to link a combination of C-files and Prolog files into a stand-alone executable. plld automates most of what is described in the previous sections.

In the normal usage, a copy is made of the default embedding template `\ldots/pl/include/stub.c`. The main() routine is modified to suit your application. PL\_initialise() must be passed the program-name (`argv[0]`) (Win32: the executing program can be obtained using GetModuleFileName()). The other elements of the command-line may be modified. Next, plld is typically invoked as:

```
plld -o output stubfile.c [other-c-or-o-files] [plfiles]
```

plld will first split the options into various groups for both the C-compiler and the Prolog compiler. Next, it will add various default options to the C-compiler and call it to create an executable holding the user’s C-code and the Prolog kernel. Then, it will call the SWI-Prolog compiler to create a saved state from the provided Prolog files and finally, it will attach this saved state to the created emulator to create the requested executable.

Below, it is described how the options are split and which additional options are passed.
-help
Print brief synopsis.

-pl pl prolog
Select the prolog to use. This prolog is used for two purposes: get the home-directory as well
as the compiler/linker options and create a saved state of the Prolog code.

-li linker
Linker used to link the raw executable. Default is to use the C-compiler (Win32: link.exe).

-cc C-compiler
Compiler for .c files found on the command-line. Default is the compiler used to build SWI-
Prolog accessible through the Prolog flag c_cc (Win32: cl.exe).

-c++ C++-compiler
Compiler for C++ sources (extensions .cpp, .cxx, .cc or .C) files found on the command-
line. Default is c++ or g++ if the C-compiler is gcc (Win32: cl.exe).

-nostate
Just relink the kernel, do not add any Prolog code to the new kernel. This is used to create a new
kernel holding additional foreign predicates on machines that do not support the shared-library
(DLL) interface, or if building the state cannot be handled by the default procedure used
by plld. In the latter case the state is created separately and appended to the kernel using
cat ⟨kernel⟩ ⟨state⟩ > ⟨out⟩ (Win32: copy /b ⟨kernel⟩+⟨state⟩ ⟨out⟩)

-shared
Link C, C++ or object files into a shared object (DLL) that can be loaded by the
load_fo reign_library/1 predicate. If used with -c it sets the proper options to compile a C or C++ file ready for linking into a shared object

-dll
Windows only. Embed SWI-Prolog into a DLL rather than an executable.

-c
Compile C or C++ source-files into object files. This turns plld into a replacement for the C
or C++ compiler where proper options such as the location of the include directory are passed
automatically to the compiler.

-E
Invoke the C preprocessor. Used to make plld a replacement for the C or C++ compiler.

-pl-options ... Additional options passed to Prolog when creating the saved state. The first character immediately following pl-options is used as separator and translated to spaces when the argument is built. Example: -pl-options,-F,xpce passed -F xpce as additional flags to Prolog.

-li-options ...
Passes options to the linker, similar to -pl-options.

-cc-options ...
Passes options to the C/C++ compiler, similar to -pl-options.
Select verbose operation, showing the various programs and their options.

Reserved to specify the final output file.

Specifies a library for the C-compiler. By default, -lpl (Win32: libpl.lib) and the libraries needed by the Prolog kernel are given.

Specifies a library directory for the C-compiler. By default the directory containing the Prolog C-library for the current architecture is passed.

These options are passed to the C-compiler. By default, the include directory containing SWI-Prolog.h is passed. plld adds two additional * -Ddef flags:

Indicates the code is to be connected to SWI-Prolog.

Indicates the creation of an embedded program.

Passed as input files to the C-compiler

Passed as input files to the Prolog compiler to create the saved-state.

I.e. all other options. These are passed as linker options to the C-compiler.

The following is a very simple example going through all the steps outlined above. It provides an arithmetic expression evaluator. We will call the application calc and define it in the files calc.c and calc.pl. The Prolog file is simple:

```
calc(Atom) :-
    term_to_atom(Expr, Atom),
    A is Expr,
    write(A),
    nl.
```

The C-part of the application parses the command-line options, initialises the Prolog engine, locates the calc/1 predicate and calls it. The coder is in figure 9.5.

The application is now created using the following command-line:

```
% plld -o calc calc.c calc.pl
```
```c
#include <stdio.h>
#include <SWI-Prolog.h>

#define MAXLINE 1024

int
main(int argc, char **argv)
{
    char expression[MAXLINE];
    char *e = expression;
    char *program = argv[0];
    char *plav[2];
    int n;

    /* combine all the arguments in a single string */
    for(n=1; n<argc; n++)
    {
        if ( n != 1 )
            *e++ = ' ';
        strcpy(e, argv[n]);
        e += strlen(e);
    }

    /* make the argument vector for Prolog */
    plav[0] = program;
    plav[1] = NULL;

    /* initialise Prolog */
    if ( !PL_initialise(1, plav) )
        PL_halt(1);

    /* Lookup calc/1 and make the arguments and call */
    { predicate_t pred = PL_predicate("calc", 1, "user");
      term_t h0 = PL_new_term_refs(1);
      int rval;

      PL_put_atom_chars(h0, expression);
      rval = PL_call_predicate(NULL, PL_Q_NORMAL, pred, h0);

      PL_halt(rval ? 0 : 1);
    }

    return 0;
}
```

Figure 9.5: C-source for the calc application
The following indicates the usage of the application:

% calc pi/2
1.5708

9.8 The Prolog ‘home’ directory

Executables embedding SWI-Prolog should be able to find the ‘home’ directory of the development environment unless a self-contained saved-state has been added to the executable (see qsave_program/[1,2] and section 9.7).

If Prolog starts up, it will try to locate the development environment. To do so, it will try the following steps until one succeeds.

1. If the --home=DIR is provided, use this.

2. If the environment variable SWI_HOME_DIR is defined and points to an existing directory, use this.

3. If the environment variable SWIPL is defined and points to an existing directory, use this.

4. Locate the primary executable or (Windows only) a component (module) thereof and check whether the parent directory of the directory holding this file contains the file swipl. If so, this file contains the (relative) path to the home directory. If this directory exists, use this. This is the normal mechanism used by the binary distribution.

5. If the precompiled path exists, use it. This is only useful for a source installation.

If all fails and there is no state attached to the executable or provided Windows module (see PL_initialise()), SWI-Prolog gives up. If a state is attached, the current working directory is used.

The file_search_path/2 alias swi is set to point to the home directory located.

9.9 Example of Using the Foreign Interface

Below is an example showing all stages of the declaration of a foreign predicate that transforms atoms possibly holding uppercase letters into an atom only holding lower case letters. Figure 9.6 shows the C-source file, figure 9.7 illustrates compiling and loading of foreign code.
/* Include file depends on local installation */
#include <SWI-Prolog.h>
#include <stdlib.h>
#include <string.h>
#include <ctype.h>

foreign_t
pl_lowercase(term_t u, term_t l)
{
    char *copy;
    char *s, *q;
    int rval;

    if ( !PL_get_atom_chars(u, &s) )
        return PL_warning("lowercase/2: instantiation fault");
    copy = malloc(strlen(s)+1);

    for( q=copy; *s; q++, s++)
        *q = (isupper(*s) ? tolower(*s) : *s);
    *q = '\0';

    rval = PL_unify_atom_chars(l, copy);
    free(copy);

    return rval;
}

install_t
install()
{
    PL_register_foreign("lowercase", 2, pl_lowercase, 0);
}

Figure 9.6: Lowercase source file
9.9. EXAMPLE OF USING THE FOREIGN INTERFACE

% gcc -I/usr/local/lib/pl-\plversion/include -fpic -c lowercase.c
% gcc -shared -o lowercase.so lowercase.o
% pl

   Yes

Figure 9.7: Compiling the C-source and loading the object file
9.10 Notes on Using Foreign Code

9.10.1 Memory Allocation

SWI-Prolog’s heap memory allocation is based on the malloc(3) library routines. The stacks are allocated using mmap() on most Unix machines and using VirtualAlloc() on windows. SWI-Prolog provides the functions below as a wrapper around malloc(). Allocation errors in these functions trap SWI-Prolog’s fatal-error handler, in which case PL_malloc() or PL_realloc() do not return.

Portable applications must use PL_free() to release strings returned by PL_get_chars() using the BUF_MALLOC argument. Portable applications may use both PL_malloc() and friends or malloc() and friends but should not mix these two sets of functions on the same memory.\(^9\)

```c
void * PL_malloc(size_t bytes)
Allocate bytes of memory. On failure SWI-Prolog’s fatal error handler is called and PL_malloc() does not return. Memory allocated using these functions must use PL_realloc() and PL_free() rather than realloc() and free().
```

```c
void * PL_realloc(void *mem, size_t size)
Change the size of the allocated chunk, possibly moving it. The mem argument must be obtained from a previous PL_malloc() or PL_realloc() call.
```

```c
void PL_free(void *mem)
Release memory. The mem argument must be obtained from a previous PL_malloc() or PL_realloc() call.
```

9.10.2 Compatibility between Prolog versions

Great care is taken to ensure binary compatibility of foreign extensions between different Prolog versions. Only much less frequently used stream interface has been responsible for binary incompatibilities.

Source-code that relies on new features of the foreign interface can use the macro PLVERSION to find the version of SWI-Prolog.h and PL_query() using the option PL_QUERY_VERSION to find the version of the attached Prolog system. Both follow the same numbering schema explained with PL_query().

9.10.3 Debugging and profiling foreign code (valgrind)

This section is only relevant for Unix users on platforms supported by valgrind. Valgrind is an excellent binary instrumentation platform. Unlike many other instrumentation platforms, valgrind can deal with code loaded through dlopen().

The callgrind tool can be used to profile foreign code loaded under SWI-Prolog. Compile the foreign library adding -g option to gcc or plld. By setting the environment variable VALGRIND to yes, SWI-Prolog will not release loaded shared objects using dlclose(). This trick is required to get source information on the loaded library. Without, valgrind claims that the shared object has no debugging information.\(^10\) Here is the complete sequence using bash as login shell:

\(^9\)These functions were introduced in SWI-Prolog 5.0.9 to realise guaranteed portability. Foreign code that must be compatible with older versions can check the PLVERSION macro.

\(^10\)Tested using valgrind version 3.2.3 on x64.
% VALGRIND=yes valgrind --tool=callgrind pl <args>
<prolog interaction>
% kcachegrind callgrind.out.<pid>

9.10.4 Name Conflicts in C modules

In the current version of the system all public C functions of SWI-Prolog are in the symbol table. This can lead to name clashes with foreign code. Someday I should write a program to strip all these symbols from the symbol table (why does Unix not have that?). For now I can only suggest to give your function another name. You can do this using the C preprocessor. If—for example—your foreign package uses a function warning(), which happens to exist in SWI-Prolog as well, the following macro should fix the problem.

#define warning warning_

Note that shared libraries do not have this problem as the shared library loader will only look for symbols in the main executable for symbols that are not defined in the library itself.

9.10.5 Compatibility of the Foreign Interface

The term-reference mechanism was first used by Quintus Prolog version 3. SICStus Prolog version 3 is strongly based on the Quintus interface. The described SWI-Prolog interface is similar to using the Quintus or SICStus interfaces, defining all foreign-predicate arguments of type +term. SWI-Prolog explicitly uses type functor.t, while Quintus and SICStus uses ⟨name⟩ and ⟨arity⟩. As the names of the functions differ from Prolog to Prolog, a simple macro layer dealing with the names can also deal with this detail. For example:

#define QP_put_functor(t, n, a) PL_put_functor(t, PL_new_functor(n, a))

The PL_unify.*() functions are lacking from the Quintus and SICStus interface. They can easily be emulated or the put/unify approach should be used to write compatible code.

The PL_open_foreign_frame()/PL_close_foreign_frame() combination is lacking from both other Prologs. SICStus has PL_new_term_ref(s)(0), followed by PL_reset_term_ref(s)() that allows for discarding term references.

The Prolog interface for the graphical user interface package XPCE shares about 90% of the code using a simple macro layer to deal with different naming and calling conventions of the interfaces.
This chapter describes the features of SWI-Prolog for delivering applications that can run without the development version of the system installed.

A SWI-Prolog runtime executable is a file consisting of two parts. The first part is the emulator, which is machine dependent. The second part is the resource archive, which contains the compiled program in a machine-independent format, startup options and possibly user-defined resources, see resource/3 and open_resource/3.

These two parts can be connected in various different ways. The most common way for distributed runtime applications is to concatenate the two parts. This can be achieved using external commands (Unix: `cat`, Windows: `copy`), or using the `stand_alone` option to `qsave_program/2`. The second option is to attach a startup script in front of the resource that starts the emulator with the proper options. This is the default under Unix. Finally, an emulator can be told to use a specified resource file using the `-x` command-line switch.

`qsave_program(+File, +ListOfOptions)`

Saves the current state of the program to the file `File`. The result is a resource archive containing a saved-state that expresses all Prolog data from the running program and all user-defined resources. Depending on the `stand_alone` option, the resource is headed by the emulator, a Unix shell-script or nothing.

`ListOfOptions` is a list of `<Key>=<Value>` or `<Key>(<Value>)` pairs. The available keys are described in table 10.1.

Before writing the data to file, `qsave_program/2` will run `autoload/0` to all required autoloading the system can discover. See `autoload/0`.

Provided the application does not require any of the Prolog libraries to be loaded at runtime, the only file from the SWI-Prolog development environment required is the emulator itself. The emulator may be built in two flavours. The default is the development emulator. The runtime emulator is similar, but lacks the tracer.

If the option `stand_alone(true)` is present, the emulator is the first part of the state. If the emulator is started it will test whether a boot-file (state) is attached to the emulator itself and load this state. Provided the application has all libraries loaded, the resulting executable is completely independent of the runtime environment or location where it was build.

See also section 2.10.2.

`qsave_program(+File)`

Equivalent to `qsave_program(File, [])`.

`autoload`

Check the current Prolog program for predicates that are referred to, are undefined and have a definition in the Prolog library. Load the appropriate libraries.

Table 10.1: ⟨Key⟩ = ⟨Value⟩ pairs for qsave_program/2

This predicate is used by qsave_program/[1,2] to ensure the saved state will not depend on one of the libraries. The predicate autoload/0 will find all direct references to predicates. It does not find predicates referenced via meta-predicates. The predicate log/2 is defined in the library(quintus) to provide a quintus compatible means to compute the natural logarithm of a number. The following program will behave correctly if its state is executed in an environment where the library(quintus) is not available:

```prolog
logtable(From, To) :-
   From > To, !.
logtable(From, To) :-
   log(From, Value),
   format(’~d~t~8|~2f~n’,[From, Value]),
   F is From + 1,
   logtable(F, To).
```

However, the following implementation refers to log/2 through the meta-predicate maplist/3. Autoload will not be able to find the reference. This problem may be fixed either by loading the module library(quintus) explicitly or use require/1 to tell the system that the predicate log/2 is required by this module.

```prolog
logtable(From, To) :-
   findall(X, between(From, To, X), Xlist),
```

SWI-Prolog 5.6 Reference Manual
maplist(log, Xlist, SineList),
write_table(Xlist, SineList).

write_table([], []).  
write_table([I|IT], [V|VT]) :-
    format(‘d’t’8|2f’n’, [I, V]),
    write_table(IT, VT).

volatile +Name/Arity, . . .
Declare that the clauses of specified predicates should not be saved to the program. The volatile declaration is normally used to avoid that the clauses of dynamic predicates that represent data for the current session is saved in the state file.

10.1 Limitations of qsave_program

There are three areas that require special attention when using qsave_program/1,2.

- If the program is an embedded Prolog application or uses the foreign language interface, care has to be taken to restore the appropriate foreign context. See section 10.2 for details.
- If the program uses directives (:– goal. lines) that perform other actions then setting predicate attributes (dynamic, volatile, etc.) or loading files (consult, etc.), the directive may need to be prefixed with initialization/1.
- Database references as returned by clause/3, recorded/3, etc. are not preserved and may thus not be part of the database when saved.

10.2 Runtimes and Foreign Code

Some applications may need to use the foreign language interface. Object code is by definition machine-dependent and thus cannot be part of the saved program file.

To complicate the matter even further there are various ways of loading foreign code:

- Using the library(shlib) predicates
  This is the preferred way of dealing with foreign code. It loads quickly and ensures an acceptable level of independence between the versions of the emulator and the foreign code loaded. It works on Unix machines supporting shared libraries and library functions to load them. Most modern Unixes, as well as Win32 (Windows 95/NT) satisfy this constraint.

- Static linking
  This mechanism works on all machines, but generally requires the same C-compiler and linker to be used for the external code as is used to build SWI-Prolog itself.

To make a runtime executable that can run on multiple platforms one must make runtime checks to find the correct way of linking. Suppose we have a source-file myextension.c defining the installation function install().

If this file is compiled into a shared library, load_foreign_library/1 will load this library and call the installation function to initialise the foreign code. If it is loaded as a static extension, define install() as the predicate install/0.
10.3. USING PROGRAM RESOURCES

A resource is very similar to a file. Resources however can be represented in two different formats: on files, as well as part of the resource archive of a saved-state (see qsave_program/2).

A resource has a name and a class. The source data of the resource is a file. Resources are declared by declaring the predicate resource/3. They are accessed using the predicate open_resource/3.

Before going into details, let us start with an example. Short texts can easily be expressed in Prolog source code, but long texts are cumbersome. Assume our application defines a command 'help' that prints a helptext to the screen. We put the content of the helptext into a file called help.txt. The following code implements our help command such that help.txt is incorporated into the runtime executable.

resource(help, text, 'help.txt').

help :-
    open_resource(help, text, In),
    call_cleanup(copy_stream_data(In, user_output),
                close(In)).
The predicate `help/0` opens the resource as a Prolog stream. If we are executing this from the development environment, this will actually return a stream to the file `help.txt` itself. When executed from the saved-state, the stream will actually be a stream opened on the program resource file, taking care of the offset and length of the resource.

10.3.1 Predicates Definitions

**resource(+Name, +Class, +FileSpec)**

This predicate is defined as a dynamic predicate in the module `user`. Clauses for it may be defined in any module, including the user module. `Name` is the name of the resource (an atom). A resource name may contain any character, except for `$` and `:`, which are reserved for internal usage by the resource library. `Class` describes the what kind of object is stored in the resource. In the current implementation, it is just an atom. `FileSpec` is a file specification that may exploit `file_search_path/2` (see `absolute_file_name/2`).

Normally, resources are defined as unit clauses (facts), but the definition of this predicate also allows for rules. For proper generation of the saved state, it must be possible to enumerate the available resources by calling this predicate with all its arguments unbound.

Dynamic rules are useful to turn all files in a certain directory into resources, without specifying a resources for each file. For example, assume the `file_search_path/2 icons` refers to the resource directory containing icon-files. The following definition makes all these images available as resources:

```prolog
resource(Name, image, icons(XpmName)) :-
    atom(Name), !,
    file_name_extension(Name, xpm, XpmName).

resource(Name, image, XpmFile) :-
    var(Name),
    absolute_file_name(icons(.), [type(directory)], Dir)
    concat(Dir, '/*.xpm', Pattern),
    expand_file_name(Pattern, XpmFiles),
    member(XpmFile, XpmFiles).
```

**open_resource(+Name, ?Class, -Stream)**

Opens the resource specified by `Name` and `Class`. If the latter is a variable, it will be unified to the class of the first resource found that has the specified `Name`. If successful, `Stream` becomes a handle to a binary input stream, providing access to the content of the resource.

The predicate `open_resource/3` first checks `resource/3`. When successful it will open the returned resource source-file. Otherwise it will look in the programs resource database. When creating a saved-state, the system normally saves the resource contents into the resource archive, but does not save the resource clauses.

This way, the development environment uses the files (and modifications to the `resource/3` declarations and/or files containing resource info thus immediately affect the running environment, while the runtime system quickly accesses the system resources.
10.3.2 The plrc program

The utility program plrc can be used to examine and manipulate the contents of a SWI-Prolog resource file. The options are inspired by the Unix ar program. The basic command is:

```
% plrc option resource-file member ...
```

The options are described below.

- **l**
  List contents of the archive.

- **x**
  Extract named (or all) members of the archive into the current directory.

- **a**
  Add files to the archive. If the archive already contains a member with the same name, the contents is replaced. Anywhere in the sequence of members, the options \(--\)class=class and \(--\)encoding=encoding may appear. They affect the class and encoding of subsequent files. The initial class is data and encoding none.

- **d**
  Delete named members from the archive.

This command is also described in the pl(1) Unix manual page.

10.4 Finding Application files

If your application uses files that are not part of the saved program such as database files, configuration files, etc., the runtime version has to be able to locate these files. The file_search_path/2 mechanism in combination with the -palias command-line argument is the preferred way to locate runtime files. The first step is to define an alias for the top-level directory of your application. We will call this directory gnatdir in our examples.

A good place for storing data associated with SWI-Prolog runtime systems is below the emulator’s home-directory. swi is a predefined alias for this directory. The following is a useful default definition for the search path.

```
user:file_search_path(gnatdir, swi(gnat)).
```

The application should locate all files using absolute_file_name. Suppose gnatdir contains a file config.pl to define local configuration. Then use the code below to load this file:

```
configure_gnat :-
  ( absolute_file_name(gnatdir('config.pl'), ConfigFile)
    -> consult(ConfigFile)
  ;   format(user_error, 'gnat: Cannot locate config.pl\n'),
    halt(1)
  ).
```
10.4.1 Passing a path to the application

Suppose the system administrator has installed the SWI-Prolog runtime environment in `/usr/local/lib/rt-pl-3.2.0`. A user wants to install gnat, but gnat will look for its configuration in `/usr/local/lib/rt-pl-3.2.0/gnat` where the user cannot write.

The user decides to install the gnat runtime files in `/users/bob/lib/gnat`. For one-time usage, the user may decide to start gnat using the command:

```
% gnat -p gnatdir=/users/bob/lib/gnat
```

10.5 The Runtime Environment

10.5.1 The Runtime Emulator

The sources may be used to built two versions of the emulator. By default, the development emulator is built. This emulator contains all features for interactive development of Prolog applications. If the system is configured using `--enable-runtime`, `make` will create a runtime version of the emulator. This emulator is equivalent to the development version, except for the following features:

- **No input editing**
  The GNU library `-lreadline` that provides EMACS compatible editing of input lines will not be linked to the system.

- **No tracer**
  The tracer and all its options are removed, making the system a little faster too.

- **No profiler**
  `profile/3` and friends are not supported. This saves some space and provides better performance.

- **No interrupt**
  Keyboard interrupt (Control-C normally) is not rebound and will normally terminate the application.

- **current_prolog_flag(runtime, true) succeeds**
  This may be used to verify your application is running in the runtime environment rather than the development environment.

- **clause/[2,3]**
  do not work on static predicates] This Prolog flag inhibits listing your program. It is only a very limited protection however.

The following fragment is an example for building the runtime environment in `\env{HOME}/lib/rt-pl-3.2.0`. If possible, the shared-library interface should be configured to ensure it can serve a large number of applications.

```
% cd pl-3.2.0
% mkdir runtime
% cd runtime
```
10.5. THE RUNTIME ENVIRONMENT

% ../src/configure --enable-runtime --prefix=$HOME
% make
% make rt-install

The runtime directory contains the components listed below. This directory may be tar'ed and shipped with your application.

The SWI-Prolog library

This chapter documents the SWI-Prolog library. As SWI-Prolog provides auto-loading, there is little difference between library predicates and built-in predicates. Part of the library is therefore documented in the rest of the manual. Library predicates differ from built-in predicates in the following ways.

- User-definition of a built-in leads to a permission-error, while using the name of a library predicate is allowed.
- If autoloading is disabled explicitly or because trapping unknown predicates is disabled (see unknown/2 and current_prolog_flag/2), library predicates must be loaded explicitly.
- Using libraries reduce the footprint of applications that don’t need them.

The documentation of the library is just started. Material from the standard packages should be moved here, some material from other parts of the manual should be moved too and various libraries are not documented at all.

A.1 aggregate.pl – Aggregation operators on backtrackable predicates

**Compatibility** Quintus, SICStus 4. The forall/2 is a SWI-Prolog built-in and term_variables/3 is a SWI-Prolog with a different definition.

**To be done**
- Analysing the aggregation template and compiling a predicate for the list aggregation can be done at compile time.
- aggregate_all/3 can be rewritten to run in constant space using non-backtrackable assignment on a term.

This library provides aggregating operators over the solutions of a predicate. The operations are a generalisation of the bagof/3, setof/3 and findall/3 built-in predicates. The defined aggregation operations are counting, computing the sum, minimum, maximum, a bag of solutions and a set of solutions. We first give a simple example, computing the country with the smallest area:

```prolog
smallest_country(Name, Area) :-
    aggregate(min(A, N), country(N, A), min(Area, Name)).
```

There are four aggregation predicates, distinguished on two properties.

**aggregate vs. aggregate_all** The aggregate predicates use setof/3 (aggregate/4) or bagof/3 (aggregate/3), dealing with existential qualified variables (Var ∧ Goal) and providing multiple solutions for the remaining free variables in Goal. The aggregate_all/3
predicate uses `findall/3`, implicitly qualifying all free variables and providing exactly one solution, while `aggregate_all/4` uses `sort/2` over solutions and Distinguish (see below) generated using `findall/3`.

**The Distinguish argument** The versions with 4 arguments provide a Distinguish argument that allow for keeping duplicate bindings of a variable in the result. For example, if we wish to compute the total population of all countries we do not want to lose results because two countries have the same population. Therefore we use:

\[
\text{aggregate}(\text{sum(P)}, \text{Name}, \text{country(Name, P)}, \text{Total})
\]

All aggregation predicates support the following operator below in Template. In addition, they allow for an arbitrary named compound term where each of the arguments is a term from the list below. I.e. the term \( r(\text{min}(X), \text{max}(X)) \) computes both the minimum and maximum binding for \( X \).

- **count**
  Count number of solutions. Same as `sum(1)`.
- **sum(Expr)**
  Sum of `Expr` for all solutions.
- **min(Expr)**
  Minimum of `Expr` for all solutions.
- **min(Expr, Witness)**
  A term \( \text{min}(\text{Min}, \text{Witness}) \), where \( \text{Min} \) is the minimal version of `Expr` over all `Solution` and `Witness` is any other template applied to `Solution` that produced `Min`. If multiple solutions provide the same minimum, `Witness` corresponds to the first solution.
- **max(Expr)**
  Maximum of `Expr` for all solutions.
- **max(Expr, Witness)**
  As `min(Expr, Witness)`, but producing the maximum result.
- **set(X)**
  An ordered set with all solutions for `X`.
- **bag(X)**
  A list of all solutions for `X`.

### Acknowledgements

*The development of this library was sponsored by SecuritEase, http://www.securitease.com*

\[
\text{aggregate}(\text{+Template}, :\text{Goal}, -\text{Result})
\]

Aggregate bindings in `Goal` according to `Template`. The `aggregate/3` version performs `bagof/3` on `Goal`. 
**aggregate(+Template, +Discriminator, :Goal, -Result)**

Aggregate bindings in `Goal` according to `Template`. The `aggregate/3` version performs `setof/3` on `Goal`.

**aggregate_all(+Template, :Goal, -Result)**

Aggregate bindings in `Goal` according to `Template`. The `aggregate_all/3` version performs `findall/3` on `Goal`.

**aggregate_all(+Template, +Discriminator, :Goal, -Result)**

Aggregate bindings in `Goal` according to `Template`. The `aggregate_all/3` version performs `findall/3` followed by `sort/2` on `Goal`.

**foreach(:Generator, :Goal)**

True if the conjunction of instances of `Goal` using the bindings from `Generator` is true. Unlike `forall/2`, which runs a failure-driven loop that proves `Goal` for each solution of `Generator`, `foreach` creates a conjunction. Each member of the conjunction is a copy of `Goal`, where the variables it shares with `Generator` are filled with the values from the corresponding solution.

The implementation executes `forall/2` if `Goal` does not contain any variables that are not shared with `Generator`.

Here is an example:

```
?- foreach(between(1,4,X), dif(X,Y)), Y = 5.
Y = 5
?- foreach(between(1,4,X), dif(X,Y)), Y = 3.
No
```

**free_variables(:Generator, +Template, +VarList0, -VarList)**

In order to handle variables properly, we have to find all the universally quantified variables in the `Generator`. All variables as yet unbound are universally quantified, unless

1. they occur in the template
2. they are bound by `X∧P`, `setof`, or `bagof`

`free_variables(Generator, Template, OldList, NewList)` finds this set, using `OldList` as an accumulator.

**author**

- Richard O’Keefe
- Jan Wielemaker (made some SWI-Prolog enhancements)

**license**

Public domain (from DEC10 library).

**To be done**

- Distinguish between control-structures and data terms.
- Exploit our built-in `term_variables/2` at some places?
A.2  apply.pl – Apply predicates on a list

See also
- apply_macros.pl provides compile-time expansion for part of this library.

To be done
- Move maplist/N from boot/apply.pl to here.
- Add include/4, include/5, exclude/4, exclude/5

This module defines meta-predicates that apply a predicate on all members of a list.

\[ \text{include}(:\text{Goal}, +\text{List1}, ?\text{List2}) \]
\[ \text{[det]} \]
Filter elements for which \text{Goal} succeed. True if \text{List2} contains those elements \text{Xi} of \text{List1} for which call(\text{Goal, Xi}) succeeds.

See also  Older versions of SWI-Prolog had sublist/3 with the same arguments and semantics.

\[ \text{exclude}(:\text{Goal}, +\text{List1}, ?\text{List2}) \]
\[ \text{[det]} \]
Filter elements for which \text{Goal} fails. True if \text{List2} contains those elements \text{Xi} of \text{List1} for which call(\text{Goal, Xi}) fails.

\[ \text{partition}(:\text{Pred}, +\text{List}, ?\text{Included}, ?\text{Excluded}) \]
\[ \text{[det]} \]
Filter elements of \text{List} according to \text{Pred}. True if \text{Included} contains all elements for which call(\text{Pred, X}) succeeds and \text{Excluded} contains the remaining elements.

\[ \text{partition}(:\text{Pred}, +\text{List}, ?\text{Less}, ?\text{Equal}, ?\text{Greater}) \]
\[ \text{[semidet]} \]
Filter list according to \text{Pred} in three sets. For each element \text{Xi} of \text{List}, its destination is determined by call(\text{Pred, Xi, Place}), where \text{Place} must be unified to one of \text{<, = or >}. \text{Pred} must be deterministic.

A.3  assoc: Association lists

Authors: Richard A. O’Keefe, L.Damas, V.S.Costa and Markus Triska

Elements of an association list have 2 components: A (unique) key and a value. Keys should be ground, values need not be. An association list can be used to fetch elements via their keys and to enumerate its elements in ascending order of their keys. The assoc module uses AVL trees to implement association lists. This makes inserting, changing and fetching a single element an O(log(N)) (where N denotes the number of elements in the list) expected time (and worst-case time) operation.

\[ \text{assoc_to_list}(+\text{Assoc}, -\text{List}) \]
\[ \text{List} \text{ is a list of Key-Value pairs corresponding to the associations in } \text{Assoc} \text{ in ascending order of keys.} \]

\[ \text{assoc_to_keys}(+\text{Assoc}, -\text{List}) \]
\[ \text{List} \text{ is a list of Keys corresponding to the associations in } \text{Assoc} \text{ in ascending order.} \]

\[ \text{assoc_to_values}(+\text{Assoc}, -\text{List}) \]
\[ \text{List} \text{ is a list of Values corresponding to the associations in } \text{Assoc} \text{ in ascending order of the keys they are associated to.} \]
empty_assoc(-Assoc)
   Assoc is unified with an empty association list.

gen_assoc(?Key, +Assoc, ?Value)
   Enumerate matching elements of Assoc in ascending order of their keys via backtracking.

get_assoc(+Key, +Assoc, ?Value)
   Value is the value associated with Key in the association list Assoc.

get_assoc(+Key, +Assoc, ?Old, ?NewAssoc, ?New)
   NewAssoc is an association list identical to Assoc except that the value associated with Key is New instead of Old.

list_to_assoc(+List, ?Assoc)
   Assoc is an association list corresponding to the Key-Value pairs in List.

map_assoc(:Goal, +Assoc)
   Goal(V) is true for every value V in Assoc.

map_assoc(:Goal, +AssocIn, ?AssocOut)
   AssocOut is AssocIn with Goal applied to all corresponding pairs of values.

max_assoc(+Assoc, ?Key, ?Value)
   Key and Value are key and value of the element with the largest key in Assoc.

min_assoc(+Assoc, ?Key, ?Value)
   Key and Value are key and value of the element with the smallest key in Assoc.

ord_list_to_assoc(+List, ?Assoc)
   Assoc is an association list corresponding to the Key-Value pairs in List, which must occur in ascending order of their keys.

put_assoc(+Key, +Assoc, +Value, ?NewAssoc)
   NewAssoc is an association list identical to Assoc except that Key is associated with Value. This can be used to insert and change associations.

A.4 broadcast: Broadcast and receive event notifications

The broadcast library was invented to realise GUI applications consisting of stand-alone components that use the Prolog database for storing the application data. Figure A.1 illustrates the flow of information using this design.

The broadcasting service provides two services. Using the ‘shout’ service, an unknown number of agents may listen to the message and act. The broadcaster is not (directly) aware of the implications. Using the ‘request’ service, listening agents are asked for an answer one-by-one and the broadcaster is allowed to reject answers using normal Prolog failure.

Shouting is often used to inform about changes made to a common database. Other messages can be “save yourself” or “show this”.

Requesting is used to get information while the broadcaster is not aware who might be able to answer the question. For example “who is showing X?”. 
broadcast(+Term)

Broadcast *Term*. There are no limitations to *Term*, though being a global service, it is good practice to use a descriptive and unique principal functor. All associated goals are started and regardless of their success or failure, broadcast/1 always succeeds. Exceptions are passed.

broadcast_request(+Term)

Unlike broadcast/1, this predicate stops if an associated goal succeeds. Backtracking causes it to try other listeners. A broadcast request is used to fetch information without knowing the identity of the agent providing it. C.f. “Is there someone who knows the age of John?” could be asked using

```
..., broadcast_request(age_of('John', Age)),
```

If there is an agent (*listener*) that registered an ‘age-of’ service and knows about the age of ‘John’ this question will be answered.

listen(+Template, :Goal)

Register a *listen* channel. Whenever a term unifying *Template* is broadcasted, call *Goal*. The following example traps all broadcasted messages as a variable unifies to any message. It is commonly used to debug usage of the library.

```
?- listen(Term, (writeln(Term), fail)).
?- broadcast(hello(world)).
hello(world)
```

Yes
listen(+Listener, +Template, :Goal)

Declare Listener as the owner of the channel. Unlike a channel opened using listen/2, channels that have an owner can terminate the channel. This is commonly used if an object is listening to broadcast messages. In the example below we define a ‘name-item’ displaying the name of an identifier represented by the predicate name_of/2.

:- pce_begin_class(name_item, text_item).

variable(id, any, get, "Id visualised").

initialise(NI, Id:any) :-
    name_of(Id, Name),
    send_super(NI, initialise, name, Name, message(NI, set_name, @arg1)),
    send(NI, slot, id, Id),
    listen(NI, name_of(Id, Name),
    send(NI, selection, Name)).

unlink(NI) :-
    unlisten(NI),
    send_super(NI, unlink).

set_name(NI, Name:name) :-
    get(NI, id, Id),
    retractall(name_of(Id, _)),
    assert(name_of(Id, Name)),
    broadcast(name_of(Id, Name)).

:- pce_end_class.

unlisten(+Listener)

Deregister all entries created with listen/3 whose Listener unify.

unlisten(+Listener, +Template)

Deregister all entries created with listen/3 whose Listener and Template unify.

unlisten(+Listener, +Template, :Goal)

Deregister all entries created with listen/3 whose Listener, Template and Goal unify.

listening(?Listener, ?Template, ?Goal)

Examine the current listeners. This predicate is useful for debugging purposes.

A.5 check: Elementary completeness checks

This library defines the predicate check/0 and a few friends that allow for a quick-and-dirty cross-referencing.
A.6. **CLP/CLP\_DISTINCT: WEAK ARC CONSISTENT ‘ALL\_DISTINCT’ CONSTRAINT**

**check**

Performs the three checking passes implemented by list\_undefined/0, list\_autoload/0 and list\_redefined/0. Please check the definition of these predicates for details.

The typical usage of this predicate is right after loading your program to get a quick overview on the completeness and possible conflicts in your program.

**list\_undefined**

Scans the database for predicates that have no definition. A predicate is considered defined if it has clauses, is declared using dynamic/1 or multifile/1. As a program is compiled calls are translated to predicates. If the called predicate is not yet defined it is created as a predicate without definition. The same happens with runtime generated calls. This predicate lists all such undefined predicates that are referenced and not defined in the library. See also list\_autoload/0. Below is an example from a real program and an illustration how to edit the referencing predicate using edit/1.

?- list\_undefined.
Warning: The predicates below are not defined. If these are defined
Warning: at runtime using assert/1, use :- dynamic Name/Arity.
Warning:
Warning: rdf\_edit:rdfe\_retract/4, which is referenced by
Warning: 1-st clause of rdf\_edit:undo/4
Warning: rdf\_edit:rdfe\_retract/3, which is referenced by
Warning: 1-st clause of rdf\_edit:delete\_object/1
Warning: 1-st clause of rdf\_edit:delete\_subject/1
Warning: 1-st clause of rdf\_edit:delete\_predicate/1

?- edit(rdf\_edit:undo/4).

**list\_autoload**

Lists all undefined (see list\_undefined/0) predicates that have a definition in the library along with the file from which they will be autoloaded when accessed. See also autoload/0.

**list\_redefined**

Lists predicates that are defined in the global module user as well as in a normal module. I.e. predicates for which the local definition overrules the global default definition.

---

**A.6 clp/clp\_distinct: Weak arc consistent ‘all\_distinct’ constraint**

The clp/clp\_distinct module provides the following constraints:

<table>
<thead>
<tr>
<th>constraint</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>all_distinct(+Vars)</td>
<td>The variables in Vars are constrained to be pairwise distinct. All variables must already be assigned domains (via vars_in/2 or vars_in/3) when this constraint is posted.</td>
</tr>
</tbody>
</table>

---

Author: *Markus Triska*
vars_in(+Vars, +Domain)
   Where Vars is a list of variables and Domain is a list of non-negative integers. Each variable of Vars is constrained to be in Domain.

vars_in(+Vars, +From, +To)
   Where Vars is a list of variables, and 0 ≤ From ≤ To. Each variable in Vars is constrained to be in the discrete interval [From,To].

A.6.1 Example 1

The all_distinct/1 constraint can detect various inconsistencies:

?- vars_in([X,Y,Z], [1,2]), all_distinct([X,Y,Z]).

No

A.6.2 Example 2

In this example, 3 is assigned to Z without labeling any variables:

?- vars_in([X,Y], [1,2]), vars_in([Z], [1,2,3]), all_distinct([X,Y,Z]).
   X = _G180{1-2}
   Y = _G183{1-2}
   Z = 3 ;

A.6.3 Example 3

The clp_distinct module can be used in conjunction with clp/bounds. All relevant variables must still be assigned domains via one of the vars_in predicates before all_distinct/1 can be posted:

:- use_module(library(bounds)).
:- use_module(library(clp_distinct)).

?- [X,Y] in 1..2, vars_in([X,Y], [1,2]), all_distinct([X,Y]), label([X,Y]).
   X = 1
   Y = 2 ;
   X = 2
   Y = 1 ;
A.7 clpfd.pl – Constraint Logic Programming over Finite Domains

author Markus Triska

Constraint programming is a declarative formalism that lets you describe conditions a solution must satisfy. This library provides CLP(FD), Constraint Logic Programming over Finite Domains. It can be used to model and solve various combinatorial problems such as planning, scheduling and allocation tasks.

Most predicates of this library are finite domain constraints, which are relations over integers. They generalise arithmetic evaluation of integer expressions in that propagation can proceed in all directions. This library also provides enumeration predicates, which let you systematically search for solutions on variables whose domains have become finite. A finite domain expression is one of:

- an integer
- a variable
- -Expr
- Expr + Expr
- Expr * Expr
- Expr - Expr
- min(Expr,Expr)
- max(Expr,Expr)
- Expr mod Expr
- abs(Expr)
- Expr / Expr

The most important finite domain constraints are:

<table>
<thead>
<tr>
<th>Constraint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Expr1 #&gt;= Expr2</td>
<td>Expr1 is larger than or equal to Expr2</td>
</tr>
<tr>
<td>Expr1 #=&lt; Expr2</td>
<td>Expr1 is smaller than or equal to Expr2</td>
</tr>
<tr>
<td>Expr1 #= Expr2</td>
<td>Expr1 equals Expr2</td>
</tr>
<tr>
<td>Expr1 #= Expr2</td>
<td>Expr1 is not equal to Expr2</td>
</tr>
<tr>
<td>Expr1 #&gt; Expr2</td>
<td>Expr1 is strictly larger than Expr2</td>
</tr>
<tr>
<td>Expr1 #&lt; Expr2</td>
<td>Expr1 is strictly smaller than Expr2</td>
</tr>
</tbody>
</table>

The constraints \n/2, #=/2, #\=/>2, #<</2, and #>=</2 can be reified, which means reflecting their truth values into Boolean values represented by the integers 0 and 1. Let P and Q denote reifiable constraints or Boolean variables, then:

<table>
<thead>
<tr>
<th>Constraint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#\ Q</td>
<td>True iff Q is false</td>
</tr>
<tr>
<td>P #\ / Q</td>
<td>True iff either P or Q</td>
</tr>
<tr>
<td>P #\ \ Q</td>
<td>True iff both P and Q</td>
</tr>
<tr>
<td>P #&lt;==&gt; Q</td>
<td>True iff P and Q are equivalent</td>
</tr>
<tr>
<td>P #==&gt; Q</td>
<td>True iff P implies Q</td>
</tr>
<tr>
<td>P #&lt;=&lt; Q</td>
<td>True iff Q implies P</td>
</tr>
</tbody>
</table>

The constraints of this table are reifiable as well. If a variable occurs at the place of a constraint that is being reified, it is implicitly constrained to the Boolean values 0 and 1. Therefore, the following queries all fail: ?- #\ 2., ?- #\ #\ 2. etc.
A common usage of this library is to first post the desired constraints among the variables of a model, and then to use enumeration predicates to search for solutions. As an example of a constraint satisfaction problem, consider the cryptoarithmetic puzzle \text{SEND} + \text{MORE} = \text{MONEY}, where different letters denote distinct integers between 0 and 9. It can be modeled in CLP(FD) as follows:

```prolog
:- use_module(library(clpfd)).
puzzle(\[S,E,N,D\] + \[M,O,R,E\] = \[M,O,N,E,Y\]) :-
    Vars = \[S,E,N,D,M,O,R,Y\],
    Vars ins 0..9,
    all_different(Vars),
    S*1000 + E*100 + N*10 + D +
    M*1000 + O*100 + R*10 + E #= 
    M*10000 + O*1000 + N*100 + E*10 + Y,
    M \#\= 0, S \#\= 0.
```

Sample query and its result:

```prolog
?- puzzle(As+Bs=Cs).
As = \[9, _G10107, _G10110, _G10113\],
Bs = \[1, 0, _G10128, _G10107\],
Cs = \[1, 0, _G10110, _G10107, _G10152\],
   _G10107 in 4..7,
   1000*9+91*_G10107+ -90*_G10110+_G10113+ -9000*1+ -900*0+10*_G10128+ -1*_G10152#=0,
   all_different([_G10107, _G10110, _G10113, _G10128, _G10152, 0, 1, 9]),
   _G10110 in 5..8,
   _G10113 in 2..8,
   _G10128 in 2..8,
   _G10152 in 2..8.

Here, the constraint solver has deduced more stringent bounds for all variables. Keeping the modeling part separate from the search allows to view these residual goals, observe termination and determinism properties of the modeling part in isolation from the search, and to more easily experiment with different search strategies. Labeling can then be used to search for solutions:

```prolog
?- puzzle(As+Bs=Cs), label(As).
As = \[9, 5, 6, 7\],
Bs = \[1, 0, 8, 5\],
Cs = \[1, 0, 6, 5, 2\] ;
false.
```

In this case, it suffices to label a subset of variables to find the puzzle’s unique solution, since the constraint solver is strong enough to reduce the domains of remaining variables to singleton sets. In general though, it is necessary to label all variables to obtain ground solutions.

It is perfectly reasonable to use CLP(FD) constraints instead of ordinary integer arithmetic with \text{is/2}, \text{+/2} etc. For example:
:- use_module(library(clpfd)).

fac(0, 1).
fac(N, F) :- N #> 0, N1 #= N - 1, F #= N * F1, fac(N1, F1).

This predicate can be used in all directions. For example:

?- fac(47, F).
F = 258623241511168180642964355153611979969197632389120000000000 ;
false.

?- fac(N, 1).
N = 0 ;
N = 1 ;
false.

?- fac(N, 3).
false.

To make the predicate terminate if any argument is instantiated, add the (implied) constraint F #\= 0 before the recursive call. Otherwise, the query fac(N, 0) is the only non-terminating case of this kind.

This library uses goal_expansion/2 to rewrite constraints at compilation time. The expansion’s aim is to transparently bring the performance of CLP(FD) constraints close to that of conventional arithmetic predicates (\(<\)/2, \(=:=\)/2, \(\text{is}/2\) etc.) when the constraints are used in modes that can also be handled by built-in arithmetic. To disable the expansion, set the flag clpfd_goal_expansion to false.

Use call_residue_vars/2 and copy_term/3 to inspect residual goals and the constraints in which a variable is involved. This library also provides reflection predicates (like \(\text{fd_dom}/2\), \(\text{fd_size}/2\) etc.) with which you can inspect a variable’s current domain. These predicates can be useful if you want to implement your own labeling strategies.

You can also define custom constraints. The mechanism to do this is not yet finalised, and we welcome suggestions and descriptions of use cases that are important to you. As an example of how it can be done currently, let us define a new custom constraint ”on地说ond(X,Y,Z)”, where Z shall be 1 if at least one of X and Y is instantiated:

:- use_module(library(clpfd)).

:- multifile clpfd:run_propagator/2.

on地说ond(X, Y, Z) :-
  clpfd:make_propagator(on地说ond(X, Y, Z), Prop),
  clpfd:init_propagator(X, Prop),
  clpfd:init_propagator(Y, Prop),
  clpfd:trigger_once(Prop).

clpfd:run_propagator(on地说ond(X, Y, Z), MState) :-
( integer(X) -> clpfd:kill(MState), Z = 1 ; integer(Y) -> clpfd:kill(MState), Z = 1 ; true ).

First, clpfd:make_propagator/2 is used to transform a user-defined representation of the new constraint to an internal form. With clpfd:init_propagator/2, this internal form is then attached to X and Y. From now on, the propagator will be invoked whenever the domains of X or Y are changed. Then, clpfd:trigger_once/1 is used to give the propagator its first chance for propagation even though the variables’ domains have not yet changed. Finally, clpfd:run_propagator/2 is extended to define the actual propagator. As explained, this predicate is automatically called by the constraint solver. The first argument is the user-defined representation of the constraint as used in clpfd:make_propagator/2, and the second argument is a mutable state that can be used to prevent further invocations of the propagator when the constraint has become entailed, by using clpfd:kill/1. An example of using the new constraint:

?- oneground(X, Y, Z), Y = 5.
Y = 5,
Z = 1,
X in inf..sup.

?Var in +Domain
Var is an element of Domain. Domain is one of:

Integer
Singleton set consisting only of Integer.

Lower .. Upper
All integers I such that Lower =< I =< Upper. Lower must be an integer or the atom inf, which denotes negative infinity. Upper must be an integer or the atom sup, which denotes positive infinity.

Domain1 \ Domain2
The union of Domain1 and Domain2.

+Vars ins +Domain
The variables in the list Vars are elements of Domain.

indomain(?Var)
Bind Var to all feasible values of its domain on backtracking. The domain of Var must be finite.

label(+Vars)
Equivalent to labeling([], Vars).

labeling(+Options, +Vars)
Labeling means systematically trying out values for the finite domain variables Vars until all of them are ground. The domain of each variable in Vars must be finite. Options is a list of
options that let you exhibit some control over the search process. Several categories of options exist:
The variable selection strategy lets you specify which variable of \textit{Vars} should be labeled next and is one of:

\textbf{leftmost}  
Label the variables in the order they occur in \textit{Vars}. This is the default.

\textbf{ff}  
\textit{First fail}. Label the leftmost variable with smallest domain next, in order to detect infeasibility early. This is often a good strategy.

\textbf{ffc}  
Of the variables with smallest domains, the leftmost one participating in most constraints is labeled next.

\textbf{min}  
Label the leftmost variable whose lower bound is the lowest next.

\textbf{max}  
Label the leftmost variable whose upper bound is the highest next.

The value order is one of:

\textbf{up}  
Try the elements of the chosen variable’s domain in ascending order. This is the default.

\textbf{down}  
Try the domain elements in descending order.

The branching strategy is one of:

\textbf{step}  
For each variable \(X\), a choice is made between \(X = V\) and \(X \neq V\), where \(V\) is determined by the value ordering options. This is the default.

\textbf{enum}  
For each variable \(X\), a choice is made between \(X = V_1, X = V_2\) etc., for all values \(V_i\) of the domain of \(X\). The order is determined by the value ordering options.

\textbf{bisect}  
For each variable \(X\), a choice is made between \(X \leq M\) and \(X > M\), where \(M\) is the midpoint of the domain of \(X\).

At most one option of each category can be specified, and an option must not occur repeatedly.
The order of solutions can be influenced with:

\textbf{min(Expr)}

\textbf{max(Expr)}
This generates solutions in ascending/descending order with respect to the evaluation of the arithmetic expression Expr. Labeling Vars must make Expr ground. If several such options are specified, they are interpreted from left to right, e.g.:

?- [X,Y] ins 10..20, labeling([max(X),min(Y)],[X,Y]).

This generates solutions in descending order of X, and for each binding of X, solutions are generated in ascending order of Y. To obtain the incomplete behaviour that other systems exhibit with "maximize(Expr)" and "minimize(Expr)", use once/1, e.g.:

once(labeling([max(Expr)], Vars))

Labeling is always complete, always terminates, and yields no redundant solutions.

all_different(+Vars)

Vars are pairwise distinct.

sum(+Vars, +Rel, +Expr)

The sum of elements of the list Vars is in relation Rel to Expr. For example:

?- [A,B,C] ins 0..sup, sum([A,B,C], #=, 100).
A in 0..100,
A+B+C#=100,
B in 0..100,
C in 0..100.

?X #>= ?Y
X is greater than or equal to Y.

?X #=< ?Y
X is less than or equal to Y.

?X #= ?Y
X equals Y.

?X #\= ?Y
X is not Y.

?X #> ?Y
X is greater than Y.

?X #< ?Y
X is less than Y. In addition to its regular use in problems that require it, this constraint can also be useful to eliminate uninteresting symmetries from a problem. For example, all possible matches between pairs built from four players in total:

?- Vs = [A,B,C,D], Vs ins 1..4, all_different(Vs), A #< B, C #< D, A #< C, findall(pair(A,B)-pair(C,D), label(Vs), Ms).
Ms = [pair(1, 2)-pair(3, 4), pair(1, 3)-pair(2, 4), pair(1, 4)-pair(2, 3)]
The reifiable constraint $Q$ does not hold. For example, to obtain the complement of a domain:

```prolog
?- \ X in -3..0\10..80.
 X in inf.. -4\1..9\81..sup.
```

$P \#<==\ #Q$

$P$ and $Q$ are equivalent. For example:

```prolog
?- X #= 4 \= B, X \= 4.
 B = 0,
 X in inf..3\5..sup.
```

$P \implies Q$

$P$ implies $Q$.

$Q \implies P$

$P \lor Q$ holds. For example, the sum of natural numbers below 1000 that are multiples of 3 or 5:

```prolog
?- N mod 3 #= 0 \= N mod 5 #= 0, N in 0..999, findall(N, indomain(N), Ns), sum(Ns, #=, Sum).
Ns = [0, 3, 5, 6, 9, 10, 12, 15, 18|...],
Sum = 233168
```

```prolog
lex_chain(+Lists)
```

Lists are lexicographically non-decreasing.

```prolog
tuples_in(+Tuples, +Relation)
```

Relation must be a list of lists of integers. The elements of the list Tuples are constrained to be elements of Relation. Arbitrary finite relations, such as compatibility tables, can be modeled in this way. For example, if 1 is compatible with 2 and 5, and 4 is compatible with 0 and 3:

```prolog
?- tuples_in([[X,Y]], [[1,2],[1,5],[4,0],[4,3]]), X = 4.
 X = 4,
 Y in 0\3.
```

As another example, consider a train schedule represented as a list of quadruples, denoting departure and arrival places and times for each train. In the following program, $P$ is a feasible journey of length 3 from A to D via trains that are part of the given schedule.
:- use_module(library(clpfd)).

trains([[1,2,0,1],[2,3,4,5],[2,3,0,1],[3,4,5,6],[3,4,2,3],[3,4,8,9]]).

threepath(A, D, Ps) :-
    Ps = [[A,B,_T0,T1],[B,C,T2,T3],[C,D,T4,_T5]],
    T2 #> T1,
    T4 #> T3,
    trains(Ts),
    tuples_in(Ps, Ts).

In this example, the unique solution is found without labeling:

?- threepath(1, 4, Ps).
Ps = [[1, 2, 0, 1], [2, 3, 4, 5], [3, 4, 8, 9]].

all_distinct(+Ls)
Like all_different/1, with stronger propagation.

serialized(+Starts, +Durations)
Constrain a set of intervals to a non-overlapping sequence. Starts = [S_1,...,S_n], is a list of variables or integers, Durations = [D_1,...,D_n] is a list of non-negative integers. Constrains Starts and Durations to denote a set of non-overlapping tasks, i.e.: S_i + D_i <= S_j or S_j + D_j <= S_i for all 1 <= i < j <= n.

See also Dorndorf et al. 2000, "Constraint Propagation Techniques for the Disjunctive Scheduling Problem"

element(?N, +Is, ?I)
The N-th element of the list of integers Is is I. Analogous to nth1/3.

zcompare(?Order, ?A, ?B)
Analogous to compare/3, with finite domain variables A and B. Example:

fac(N, F) :-
    zcompare(C, N, 0),
    fac_(C, N, F).

fac_(=, _, 1).
fac_(>, N, F) :- F #= F0*N, N1 #= N - 1, fac(N1, F0).

This version is deterministic if the first argument is instantiated:

?- fac(30, F).
F = 265252859812191058636308480000000.

fd_var(+Var)
True iff Var is a CLP(FD) variable.
A.8. CLPQR: CONSTRAINT LOGIC PROGRAMMING OVER RATIONALS AND REALS

fd_inf(+Var, -Inf)
    Inf is the infimum of the current domain of Var.

fd_sup(+Var, -Sup)
    Sup is the supremum of the current domain of Var.

fd_size(+Var, -Size)
    Size is the number of elements of the current domain of Var, or the atom sup if the domain is unbounded.

fd_dom(+Var, -Dom)
    Dom is the current domain (see in/2) of Var. This predicate is useful if you want to reason about domains. It is not needed if you only want to display remaining domains; instead, separate your model from the search part and let the toplevel display this information via residual goals.

A.8 clpqr: Constraint Logic Programming over Rationals and Reals

Author: Leslie De Koninck, K.U. Leuven

This CLP(Q,R) system is a port of the CLP(Q,R) system of Sicstus Prolog by Christian Holzbaur: Holzbaur C.: OFAI clp(q,r) Manual, Edition 1.3.3, Austrian Research Institute for Artificial Intelligence, Vienna, TR-95-09, 1995.\(^1\) This manual is roughly based on the manual of the above mentioned CLP(Q,R) implementation.

The CLP(Q,R) system consists of two components: the CLP(Q) library for handling constraints over the rational numbers and the CLP(R) library for handling constraints over the real numbers (using floating point numbers as representation). Both libraries offer the same predicates (with exception of bb_inf/4 in CLP(Q) and bb_inf/5 in CLP(R)). It is allowed to use both libraries in one program, but using both CLP(Q) and CLP(R) constraints on the same variable will result in an exception.

Please note that the clpqr library is not an autoload library and therefore this library must be loaded explicitly before using it:

```prolog
:- use_module(library(clpq)).
```

or

```prolog
:- use_module(library(clpr)).
```

A.8.1 Solver predicates

The following predicates are provided to work with constraints:

\{\}(+Constraints)
    Adds the constraints given by Constraints to the constraint store.

\(^1\)http://www.ai.univie.ac.at/cgi-bin/tr-online?number+95-09
entailed(+Constraint)
Succeeds if Constraint is necessarily true within the current constraint store. This means that adding the negation of the constraint to the store results in failure.

inf(+Expression, -Inf)
Computes the infimum of Expression within the current state of the constraint store and returns that infimum in Inf. This predicate does not change the constraint store.

sup(+Expression, -Sup)
Computes the supremum of Expression within the current state of the constraint store and returns that supremum in Sup. This predicate does not change the constraint store.

minimize(+Expression)
Minimizes Expression within the current constraint store. This is the same as computing the infimum and equating the expression to that infimum.

maximize(+Expression)
Maximizes Expression within the current constraint store. This is the same as computing the supremum and equating the expression to that supremum.

bb_inf(+Ints, +Expression, -Inf, -Vertex, +Eps)
This predicate is offered in CLP(R) only. It computes the infimum of Expression within the current constraint store, with the additional constraint that in that infimum, all variables in Ints have integral values. Vertex will contain the values of Ints in the infimum. Eps denotes how much a value may differ from an integer to be considered an integer. E.g. when Eps = 0.001, then X = 4.999 will be considered as an integer (5 in this case). Eps should be between 0 and 0.5.

bb_inf(+Ints, +Expression, -Inf, -Vertex)
This predicate is offered in CLP(Q) only. It behaves the same as bb_inf/5 but does not use an error margin.

bb_inf(+ints, +Expression, -Inf)
The same as bb_inf/5 or bb_inf/4 but without returning the values of the integers. In CLP(R), an error margin of 0.001 is used.

dump(+Target, +Newvars, -CodedAnswer)
Returns the constraints on Target in the list CodedAnswer where all variables of Target have been replaced by NewVars. This operation does not change the constraint store. E.g. in

dump([X, Y, Z], [x, y, z], Cons)

Cons will contain the constraints on X, Y and Z where these variables have been replaced by atoms x, y and z.

A.8.2 Syntax of the predicate arguments
The arguments of the predicates defined in the subsection above are defined in table A.1. Failing to meet the syntax rules will result in an exception.
Table A.1: CLP(Q,R) constraint BNF

| Constraints   | ::= | (Constraint) | single constraint |
|              | | (Constraint) , (Constraints) | conjunction |
|              | | (Constraint) ; (Constraints) | disjunction |
| Constraint   | ::= | (Expression) < (Expression) | less than |
|              | | (Expression) > (Expression) | greater than |
|              | | (Expression) =< (Expression) | less or equal |
|              | | (Expression) <= (Expression) | less or equal |
|              | | (Expression) >= (Expression) | greater or equal |
|              | | (Expression) != (Expression) | not equal |
|              | | (Expression) == (Expression) | equal |
| Expression   | ::= | (Variable) | Prolog variable |
|              | | (Number) | Prolog number (float, integer) |
|              | | +(Expression) | unary plus |
|              | | -(Expression) | unary minus |
|              | | (Expression) + (Expression) | addition |
|              | | (Expression) - (Expression) | subtraction |
|              | | (Expression) * (Expression) | multiplication |
|              | | (Expression) / (Expression) | division |
|              | | abs((Expression)) | absolute value |
|              | | sin((Expression)) | sine |
|              | | cos((Expression)) | cosine |
|              | | tan((Expression)) | tangent |
|              | | exp((Expression)) | exponent |
|              | | pow((Expression)) | exponent |
|              | | (Expression) ^ (Expression) | exponent |
|              | | min((Expression), (Expression)) | minimum |
|              | | max((Expression), (Expression)) | maximum |
### A.8.3 Use of unification

Instead of using the `{}/1` predicate, you can also use the standard unification mechanism to store constraints. The following code samples are equivalent:

- **Unification with a variable**
  
  ```prolog
  {X =:= Y}
  {X = Y}
  X = Y
  ```

- **Unification with a number**
  
  ```prolog
  {X =:= 5.0}
  {X = 5.0}
  X = 5.0
  ```

### A.8.4 Non-linear constraints

The CLP(Q,R) system deals only passively with non-linear constraints. They remain in a passive state until certain conditions are satisfied. These conditions, which are called the isolation axioms, are given in table A.2.

### Table A.2: CLP(Q,R) isolating axioms

<table>
<thead>
<tr>
<th>Expression</th>
<th>Condition</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>( A = B \times C )</td>
<td>B or C is ground &lt;br&gt; A and (B or C) are ground</td>
<td>( A = 5 \times C ) or ( A = B \times 4 ) &lt;br&gt; 20 = ( 5 \times C ) or 20 = ( B \times 4 )</td>
</tr>
<tr>
<td>( A = B / C )</td>
<td>C is ground &lt;br&gt; A and B are ground</td>
<td>( A = B / 3 ) &lt;br&gt; 4 = 12 / C</td>
</tr>
<tr>
<td>( X = \text{min}(Y, Z) )</td>
<td>Y and Z are ground &lt;br&gt; A and B are ground</td>
<td>( X = \text{min}(4,3) )</td>
</tr>
<tr>
<td>( X = \text{max}(Y, Z) )</td>
<td>Y and Z are ground &lt;br&gt; A and B are ground</td>
<td>( X = \text{max}(4,3) )</td>
</tr>
<tr>
<td>( X = \text{abs}(Y) )</td>
<td>Y is ground &lt;br&gt; A and B are ground</td>
<td>( X = \text{abs}(-7) )</td>
</tr>
<tr>
<td>( X = \text{pow}(Y, Z) )</td>
<td>X and Y are ground &lt;br&gt; A and B are ground</td>
<td>( 8 = 2 \times Z ) &lt;br&gt; 8 = ( Y \times 3 )</td>
</tr>
<tr>
<td>( X = \text{exp}(Y, Z) )</td>
<td>X and Y are ground &lt;br&gt; A and B are ground</td>
<td>( X = 2 \times 3 )</td>
</tr>
<tr>
<td>( X = \sin(Y) )</td>
<td>X is ground &lt;br&gt; A and B are ground</td>
<td>1 = ( \sin(Y) )</td>
</tr>
<tr>
<td>( X = \cos(Y) )</td>
<td>Y is ground &lt;br&gt; A and B are ground</td>
<td>( X = \sin(1.5707) )</td>
</tr>
</tbody>
</table>

### A.9 debug: Some reusable code to help debugging applications

This library provides an structured alternative for putting print-statements into your source-code to trace what is going on. Debug messages are organised in *topics* that can be activated and de-activated without changing the source. In addition, if the application is compiled with the -O flag these predicates are removed using `goal_expansion/2`.

Although this library can be used through the normal demand-loading mechanism it is advised to load it explicitly before code using it to profit from goal-expansion, which removes these calls if compiled with optimisation on and records the topics from `debug/3` and `debugging/1` for `list_debug_topics/0`.
**A.10. GENSYM: GENERATE UNIQUE IDENTIFIERS**

debug(+Topic, +Format, +Args)

If `Topic` is a selected debugging topic (see debug/1) a message is printed using `print_message/2` with level informational. `Format` and `Args` are interpreted by `format/2`. Here is a typical example:

```prolog
...,
  debug(init, 'Initialised ', [Module]),
...,
```

`Topic` can be any Prolog term. Compound terms can be used to make categories of topics that can be activated using debug/1.

debugging(+Topic)

Succeeds if `Topic` is a selected debugging topic. It is intended to execute arbitrary code depending on the users debug topic selection. The construct (debugging(Topic) -> Code ; true) is removed if the code is compiled in optimise mode.

debug(+Topic)

Select all registered topics that unify with `Topic` for debugging. This call is normally used from the toplevel to activate a topic for debugging. If no matching `Topic` is registered a warning is printed and the topic is registered for debugging as matching debug statements may be loaded later. Topics are de-activated using `nodebug/1`.

nodebug(+Topic)

Deactivates topics for debugging. See debug/1 for the arguments.

list_debug_topics

List the current status of registered topics. See also debugging/0.

assertion(:Goal)

This predicate is to be compared to the C-library assert() function. By inserting this goal you explicitly state you expect `Goal` to succeed at this place. As assertion/1 calls are removed when compiling in optimized mode `Goal` should not have side-effects. Typical examples are type-tests and validating invariants defined by your application.

If `Goal` fails the system prints a message, followed by a stack-trace and starts the debugger.

In older versions of this library this predicate was called assume/1. Code using assume/1 is automatically converted while printing a warning on the first occurrence.

**A.10 gensym: Generate unique identifiers**

Gensym (Generate Symbols) is an old library for generating unique symbols (atoms). Such symbols are generated from a base atom which gets a sequence number appended. Of course there is no guarantee that ‘catch22’ is not an already defined atom and therefore one must be aware these atoms are only unique in an isolated context.

The SWI-Prolog gensym library is thread-safe. The sequence numbers are global over all threads and therefore generated atoms are unique over all threads.

**gensym(+Base, -Unique)**

Generate a unique atom from base *Base* and unify it with *Unique*. *Base* should be an atom. The first call will return ⟨*base*⟩₁, the next ⟨*base*⟩₂, etc. Note that this is no warrant that the atom is unique in the system.

**reset gensym(+Base)**

Restart generation of identifiers from *Base* at ⟨*Base*⟩₁. Used to make sure a program produces the same results on subsequent runs. Use with care.

**reset gensym**

Reset gensym for all registered keys. This predicate is available for compatibility only. New code is strongly advice to avoid the use of reset gensym or at least to reset only the keys used by your program to avoid unexpected site-effects on other components.

### A.11 lists: List Manipulation

This library provides commonly accepted basic predicates for list manipulation in the Prolog community. Some additional list manipulations are built-in. Their description is in section 4.28.

**append(?List1, ?List2, ?List3)**

Succeeds when *List3* unifies with the concatenation of *List1* and *List2*. The predicate can be used with any instantiation pattern (even three variables).

**append(?ListOfLists, ?List)**

Concatenate a list of lists. Is true if *Lists* is a list of lists, and *List* is the concatenation of these lists. *ListOfLists* must be a list of -possibly- partial lists.

**member(?Elem, ?List)**

Succeeds when *Elem* can be unified with one of the members of *List*. The predicate can be used with any instantiation pattern.

**nextto(?X, ?Y, ?List)**

Succeeds when *Y* immediatly follows *X* in *List*.

**delete(+List1, ?Elem, ?List2)**

Delete all members of *List1* that simultaneously unify with *Elem* and unify the result with *List2*.

**select(?Elem, ?List, ?Rest)**

Select *Elem* from *List* leaving *Rest*. It behaves as member/2, returning the remaining elements in *Rest*. Note that besides selecting elements from a list, it can also be used to insert elements.

**selectchk(?Elem, ?List, ?Rest)**

Semi-deterministic selection from a list. Steadfast: defines as

```prolog
selectchk(Elem, List, Rest) :-
    select(Elem, List, Rest0), !,
    Rest = Rest0.
```
A.11. LISTS: LIST MANIPULATION

nth0(?Index, ?List, ?Elem)
Succeeds when the Index-th element of List unifies with Elem. Counting starts at 0.

nth1(?Index, ?List, ?Elem)
Succeeds when the Index-th element of List unifies with Elem. Counting starts at 1.

last(?List, ?Elem)
Succeeds if Elem unifies with the last element of List. If List is a proper list last/2 is deterministic. If List has an unbound tail, backtracking will cause List to grow.²

reverse(+List1, -List2)
Reverse the order of the elements in List1 and unify the result with the elements of List2.

permutation(?List1, ?List2)
Permutation is true when List1 is a permutation of List2. The implementation can solve for List2 given List1 or List1 given List2, or even enumerate List1 and List2 together.

flatten(+List1, -List2)
Transform List1, possibly holding lists as elements into a ‘flat’ list by replacing each list with its elements (recursively). Unify the resulting flat list with List2. Example:

?- flatten([a, [b, [c, d], e]], X).
X = [a, b, c, d, e]

sumlist(+List, -Sum)
Unify Sum to the result of adding all elements in List. List must be a proper list holding numbers. See number/1 and is/2. for details on arithmetic.

max_list(+List, -Max)
True if Max is the largest number in List. See also the function max/2.

min_list(+List, -Min)
True if Min is the smallest number in List. See also the function min/2.

numlist(+Low, +High, -List)
If Low and High are integers with Low ≤ High, unify List to a list [Low, Low + 1, … High]. See also between/3.

A.11.1 Set Manipulation

The set predicates listed in this section work on ordinary unsorted lists. Note that this makes many of the operations order $N^2$. For larger sets consider the use of ordered sets as implemented by library ordsets.pl, running most these operations in order $N$. See section A.15.

is_set(+Set)
Succeeds if Set is a list (see is_list/1) without duplicates.

²The argument order of this predicate was changed in 5.1.12 for compatibility reasons.
list_to_set(+List, -Set)
Unifies Set with a list holding the same elements as List in the same order. If list contains duplicates, only the first is retained. See also sort/2. Example:

?- list_to_set([a,b,a], X)
X = [a,b]

intersection(+Set1, +Set2, -Set3)
Succeeds if Set3 unifies with the intersection of Set1 and Set2. Set1 and Set2 are lists without duplicates. They need not be ordered.

subtract(+Set, +Delete, -Result)
Delete all elements of set ‘Delete’ from ‘Set’ and unify the resulting set with ‘Result’.

union(+Set1, +Set2, -Set3)
Succeeds if Set3 unifies with the union of Set1 and Set2. Set1 and Set2 are lists without duplicates. They need not be ordered.

subset(+Subset, +Set)
Succeeds if all elements of Subset are elements of Set as well.

A.12 nbset: Non-backtrackable set

The library nb_set defines non-backtrackable sets, implemented as binary trees. The sets are represented as compound terms and manipulated using nb_setarg/3. Non-backtrackable manipulation of datastructures is not supported by a large number of Prolog implementation, but it it has several advantages over using the database. It produces less garbage, is thread-safe, reentrant and deals with exceptions without leaking data.

Similar to the assoc library keys can be any Prolog term, but it is not allowed to instantiate or modify a term.

One of the ways to use this library is to generate unique values on backtracking without generating all solutions first, for example to act as a filter between a generator producing many duplicates and an expensive test routine, as outlines below.

generate_and_test(Solution) :-
    empty_nb_set(Set),
    generate(Solution),
    add_nb_set(Solution, Set, true),
    test(Solution).

empty_nb_set(?Set)
True if Set is a non-backtrackable empty set.

add_nb_set(+Key, !Set)
Add Key to Set. If Key is already a member of Set, add_nb_set/3 succeeds without modifying Set.
A.13. **WWW_BROWSER: ACTIVATING YOUR WEB-BROWSER**

```prolog
add_nb_set(+Key, !Set, ?New)
   If Key is not in Set and New is unified to true Key is added to Set. If Key is in Set New is unified to false. It can be used for many purposes:

   add_nb_set(+, +, false) Test membership
   add_nb_set(+, +, true)  Succeed only if new member
   add_nb_set(+, +, Var)   Succeed, binding Var

gen_nb_set(+Set, -Key)
   Generate all members of Set on backtracking in the standard order of terms. To test membership, use add_nb_set/3.

size_nb_set(+Set, -Size)
   Unify Size with the number of elements in Set.

nb_set_to_list(+Set, -List)
   Unify List with a list of all elements in set in the standard order of terms (i.e. and ordered list).
```

**A.13 www_browser: Activating your Web-browser**

This library deals with the very system dependent task of opening a web page in a browser. See also `url` and the HTTP package.

```prolog
www_open_url(+URL)
   Open URL in an external web-browser. The reason to place this in the library is to centralise the maintenance on this highly platform and browser specific task. It distinguishes between the following cases:

   - **MS-Windows**
     If it detects MS-Windows it uses `win_shell/2` to open the URL. The behaviour and browser started depends on the Window and Windows-shell configuration, but in general it should be the behaviour expected by the user.

   - **Other platforms**
     On other platforms it tests the environment variable (see `getenv/2`) named BROWSER or uses netscape if this variable is not set. If the browser is either mozilla or netscape, `www_open_url/1` first tries to open a new window on a running using the `-remote` option of netscape. If this fails or the browser is neither mozilla or netscape the system simply passes the URL as first argument to the program.
```

**A.14 option.pl – Option list processing**

*See also* library(record)

*To be done*
- We should consider putting many options in an assoc or record with appropriate preprocessing to achieve better performance.
- We should provide some standard to automatic type-checking on option lists.
The library(option) provides some utilities for processing option lists. Option lists are commonly used as an alternative for many arguments. Examples built-in predicates are `open/4` and `write_term/3`. Naming the arguments results in more readable code and the list nature makes it easy to extend the list of options accepted by a predicate. Option lists come in two styles, both of which are handled by this library.

**Name(Value)** This is the preferred style.

**Name = Value** This is often used, but deprecated.

Processing options inside time critical code (loops) can cause serious overhead. One possibility is to define a record using `library(record)` and initialise this using `make_record/2`. In addition to providing good performance, this also provides type-checking and central declaration of defaults.

```prolog
:- record atts(width:integer=100, shape:oneof([box,circle])=box).
```

```prolog
process(Data, Options) :-
    make_atts(Options, Attributes),
    action(Data, Attributes).

action(Data, Attributes) :-
    atts_shape(Attributes, Shape),
    ...
```

**option(?Option, +OptionList, +Default)**
Get an option from a `OptionList`. `OptionList` can use the Name=Value as well as the Name(Value) convention.

**Parameters**

- **Option** Term of the form Name(?Value).

**option(?Option, +OptionList)**
Get an option from a `OptionList`. `OptionList` can use the Name=Value as well as the Name(Value) convention. Fails silently if the option does not appear in `OptionList`.

**select_option(?Option, +Options, -RestOptions)** [semidet]
Get and remove option from an option list. As `option/2`, removing the matching option from `Options` and unifying the remaining options with `RestOptions`.

**select_option(?Option, +Options, -RestOptions, +Default)** [det]
Get and remove option with default value. As `select_option/3`, but if `Option` is not in `Options`, its value is unified with `Default` and `RestOptions` with `Options`.

**merge_options(+New, +Old, -Merged)** [det]
Merge two option lists. `Merged` is a sorted list of options using the canonical format Name(Value) holding all options from `New` and `Old`, after removing conflicting options from `Old`.
meta_options(+IsMeta, :Options0, -Options)  \[det\]
Perform meta-expansion on options that are module-sensitive. Whether an option name is
module sensitive is determined by calling call(IsMeta, Name). Here is an example:

meta_options(is_meta, OptionsIn, Options),
... 

is_meta(callback).

A.15 ordsets: Ordered Set Manipulation

Ordered sets are lists with unique elements sorted to the standard order of terms (see sort/2). Exploiting ordering, many of the set operations can be expressed in order N rather than \(N^2\) when
dealing with unordered sets that may contain duplicates. The ordsets is available in a number of
Prolog implementations. Our predicates are designed to be compatible with common practice in the
Prolog community. The implementation is incomplete and relies partly on oset, an older ordered set
library distributed with SWI-Prolog. New applications are advices to use ordsets.

Some of these predicates match directly to corresponding list operations. It is adviced to use the
versions from this library to make clear you are operating on ordered sets.

ord_empty(?Set)
True if Set is an empty ordered set. Set unifies with the empty list.

list_to_ord_set(+List, -OrdSet)
Convert a List to an ordered set. Same as sort/2.

ord_add_element(+Set, +Element, -NewSet)
Add an element to an ordered set. NewSet is the same as Set if Element is already part of Set.

ord_del_element(+Set, +Element, -NewSet)
delete Element from Set. Succeeds without changing Set if Set does not contain Element.

ord_intersect(+Set1, +Set2)
True if the intersection of Set1 and Set2 is non-empty.

ord_intersection(+Set1, +Set2, -Intersection)
True if Intersection is the intersection of Set1 and Set2.

ord_disjoint(+Set1, +Set2)
True if Set1 and Set2 have no common element. Negation of ord_intersect/2.

ord_subtract(+Set, +Delete, -Remaining)
True if Remaining contains the elements of Set that are not in set Delete.

ord_union(+Set1, +Set2, -Union)
True if Union contains all elements from Set1 and Set2

ord_union(+Set1, +Set2, -Union, -New)
Defined as if ord_union(Set1, Set2, Union), ord_subtract(Set2, Set1, New).
ord_subset(+Sub, +Super)
    True if all elements of Sub are in Super.

ord_memberchk(+Element, +Set)
    True if Element appears in Set. Does not backtrack. Same as memberchk/2.

A.16 pairs.pl – Operations on key-value lists

author  Jan Wielemaker
See also  keysort/2, library(assoc)

This module implements common operations on Key-Value lists, also known as Pairs. Pairs have
great practical value, especially due to keysort/2 and the library assoc.pl.

This library is based on discussion in the SWI-Prolog mailinglist, including specifications from
Quintus and a library proposal by Richard O’Keefe.

pairs_keys_values(?Pairs, ?Keys, ?Values)
    True if Keys holds the keys of Pairs and Values the values.
    Deterministic if any argument is instantiated to a finite list and the others are either free or
finite lists.

pairs_values(+Pairs, -Values)
    Remove the keys from a list of Key-Value pairs. Same as pairs_keys_values(Pairs, _, Values)

pairs_keys(+Pairs, -Keys)
    Remove the values from a list of Key-Value pairs. Same as pairs_keys_values(Pairs, Keys, _)  

group_pairs_by_key(+Pairs, -Joined:list(Key-Values))
    Group values with the same key. For example:

?- group_pairs_by_key([a-2, a-1, b-4], X).

X = [a-[2,1], b-[4]]

Parameters

Pairs    Key-Value list, sorted to the standard order of terms (as
         keysort/2 does)

Joined   List of Key-Group, where Group is the list of Values associated
         with Key.

transpose_pairs(+Pairs, -Transposed)
    Swap Key-Value to Value-Key and sort the result on Value (the new key) using keysort/2.

map_list_to_pairs(:Function, +List, -Keyed)
    Create a key-value list by mapping each element of List. For example, if we have a list of lists
we can create a list of Length-List using

    map_list_to_pairs(length, ListOfLists, Pairs),

SWI-Prolog 5.6 Reference Manual
A.17 pio: Pure I/O

This library provides pure list-based I/O processing for Prolog, where the communication to the actual I/O device is performed transparently through coroutining. This module itself is just an interface to the actual implementation modules.

A.17.1 pure_input.pl – Pure Input from files

author
- Ulrich Neumerkel
- Jan Wielemaker

To be done
- Provide support for alternative input readers, e.g. reading terms, tokens, etc.
- Support non-repositioning streams, such as sockets and pipes.

This module is part of pio.pl, dealing with pure input: processing input streams from the outside world using pure predicates, notably grammar rules (DCG). Using pure predicates makes non-deterministic processing of input much simpler.

Pure input uses coroutining (freeze/2) to read input from the external source into a list on demand. The overhead of lazy reading is more than compensated for by using block reads based on read_pending_input/3.

**phrase_from_file(:Grammar, +File)**

Process the content of File using the DCG rule Grammar. The space usage of this mechanism depends on the length of the not committed part of Grammar. Committed parts of the temporary list are reclaimed by the garbage collector, while the list is extended on demand. Here is a very simple definition for searching a string in a file:

```prolog
... --> []|[_],... .
```

```prolog
file_contains(File, Pattern) :-
    phrase_from_file((..., Pattern, ...), File).
```

```prolog
match_count(File, Pattern, Count) :-
    findall(x, file_contains(File, Pattern), Xs),
    length(Xs, Count).
```

This can be called as (note that the pattern must be a string (code list)):

```prolog
?- match_count('pure_input.pl', "file", Count).
```

**phrase_from_file(:Grammar, +File, +Options)**

As phrase_from_file/2, providing additional Options. Options are passed to open/4, except for buffer_size, which is passed to set_stream/2. If not specified, the default buffer size is 512 bytes. Of particular importance are the open/4 options type and encoding.
stream_to_lazy_list (+Stream, -List)  
Create a lazy list representing the character codes in Stream. It must be possible to reposition Stream. List is a list that ends in a delayed goal. List can be unified completely transparent to a (partial) list and processed transparently using DCGs, but please be aware that a lazy list is not the same as a materialized list in all respects.

Typically, this predicate is used as a building block for more high level safe predicates such as phrase_from_file/2.

To be done  Enhance of lazy list throughout the system.

A.18  prologxref: Cross-reference data collection library

This library collects information on defined and used objects in Prolog sourcefiles. Typically these are predicates, but we expect the library to deal with other types of objects in the future. The library is a building block for tools doing dependency tracking in applications. Dependency tracking is useful to reveal the structure of an unknown program or detect missing components at compile-time, but also for program transformation or minimising a program saved-state by only saving the reachable objects.

This section gives a partial description of the library API, providing some insight in how you can use it for analysing your program. The library should be further modularized, moving its knowledge about -for example- XPCE into a different file and allowing for adding knowledge about other libraries such as Logtalk. Please do not consider this interface rock-solid.

The library is exploited by two graphical tools in the SWI-Prolog environment. The XPCE frontend started by gxref/0 and described in section 3.7 and PceEmacs (section 3.4) which exploits this library for its syntax colouring.

For all predicates described below, Source is the source that is processed. This is normally a filename in any notation acceptable to the file loading predicates (see load_files/2). Using the hooks defined in section A.18.1 it can be anything else that can be translated into a Prolog stream holding Prolog source text. Callable is a callable term (see callable/1). Callables do not carry a module qualifier unless the referred predicate is not in the module defined Source.

xref_source(+Source)  
Gather information on Source. If Source has already been processed and is still up-to-date according to the file timestamp, no action is taken. This predicate must be called on a file before information can be gathered.

xref_current_source(?Source)  
Source has been processed.

xref_clean(+Source)  
Remove the information gathered for Source

xref_defined(?Source, ?Callable, -How)  
Callable is defined in Source. How is one of
A.19. READUTIL: READING LINES, STREAMS AND FILES

- **Dynamic**: Declared dynamic at Line
- **Thread Local**: Declared thread local at Line
- **Multifile**: Declared multifile at Line
- **Local**: First clause at Line
- **Foreign**: Foreign library loaded at Line
- **Constraint**: CHR Constraint at Line
- **Imported**: Imported from File

---

**XRef Called** (?Source, ?Callable, ?By)

Callable is called in Source by By.

**XRef Exported** (?Source, ?Callable)

Callable is public (exported from the module).

**XRef Module** (?Source, ?Module)

Source is a module-file defining the given module.

**XRef Built In** (?Callable)

True if Callable is a built-in predicate. Currently this is assumed for all predicates defined in the system module and having the property built_in. Built-in predicates are not registered as ‘called’.

---

A.18.1 Extending the library

The library provides hooks for extending its rules it uses for finding predicates called by some programming construct.

**Prolog: Called By** (+Goal, -Called)

Where Goal is a non-var subgoal appearing in called object (typically a clause-body). If it succeeds it must return a list of goals called by Goal. As a special construct, if a term Callable+N is returned, N variable arguments are added to Callable before further processing. For simple meta-calls a single fact suffices. Complex rules as used in the html_write library provided by the HTTP package examine the arguments and create a list of called objects.

The current system cannot deal with the same name/arity in different modules that behave differently with respect to called arguments.

---

A.19 readutil: Reading lines, streams and files

This library contains primitives to read lines, files, multiple terms, etc. The package clib provides a shared object (DLL) named readutil. If the library can locate this shared object it will use the foreign implementation for reading character codes. Otherwise it will use a Prolog implementation. Distributed applications should make sure to deliver the readutil shared object if performance of these predicates is critical.

**Read Line to Codes** (+Stream, -Codes)

Read the next line of input from Stream and unify the result with Codes after the line has been read. A line is ended by a newline character or end-of-file. Unlike read_line_to_codes/3, this predicate removes trailing newline character.

On end-of-file the atom end_of_file is returned. See also at_end_of_stream/[0,1].
read_line_to_codes(+Stream, -Codes, ?Tail)

Difference-list version to read an input line to a list of character codes. Reading stops at the newline or end-of-file character, but unlike read_line_to_codes/2, the newline is retained in the output. This predicate is especially useful for reading a block of lines up to some delimiter. The following example reads an HTTP header ended by a blank line:

```prolog
read_header_data(Stream, Header) :-
    read_line_to_codes(Stream, Header, Tail),
    read_header_data(Header, Stream, Tail).
```

```prolog
read_header_data("\r\n", _, _) :- !.
read_header_data("\n", _, _) :- !.
read_header_data(",", _, _) :- !.
read_header_data(_, Stream, Tail) :-
    read_line_to_codes(Stream, Tail, NewTail),
    read_header_data(Tail, Stream, NewTail).
```

read_stream_to_codes(+Stream, -Codes)
Read all input until end-of-file and unify the result to Codes.

read_stream_to_codes(+Stream, -Codes, ?Tail)
Difference-list version of read_stream_to_codes/2.

read_file_to_codes(+Spec, -Codes, +Options)
Read a file to a list of character codes. Spec is a file-specification for absolute_file_name/3. Codes is the resulting code-list. Options is a list of options for absolute_file_name/3 and open/4. In addition, the option tail(Tail) is defined, forming a difference-list.

read_file_to_terms(+Spec, -Terms, +Options)
Read a file to a list of Prolog terms (see read/1). Spec is a file-specification for absolute_file_name/3. Terms is the resulting list of Prolog terms. Options is a list of options for absolute_file_name/3 and open/4. In addition, the option tail(Tail) is defined, forming a difference-list.

A.20 record: Access named fields in a term

The library record provides named access to fields in a record represented as a compound term such as point(X, Y). The Prolog world knows various approaches to solve this problem, unfortunately with no consensus. The approach taken by this library is proposed by Richard O’Keefe on the SWI-Prolog mailinglist.

The approach automates a technique commonly described in Prolog text-books, where access- and modification predicates are defined for the record type. Such predicates are subject to normal import/export as well as analysis by cross-referencers. Given the simple nature of the access predicates, an optimizing compiler can easily inline them for optimal performance.

A record is defined using the directive record/1. We introduce the library with a short example:
:- record point(x:integer=0, y:integer=0).

..., default_point(Point),
    point_x(Point, X),
    set_x_of_point(10, Point, Point1),

    make_point([y(20)], YPoint),

The principal functor and arity of the term used defines the name and arity of the compound used as records. Each argument is described using a term of the format below.

\[ name ::= \langle \text{type} \rangle [= \langle \text{default} \rangle] \]

In this definition, \langle name \rangle is an atom defining the name of the argument, \langle type \rangle is an optional type specification as defined by must_be/2 from library error and \langle default \rangle is the default initial value. The \langle type \rangle defaults to any. If no default value is specified the default is an unbound variable.

A record declaration creates a set of predicates through term-expansion. We describe these predicates below. In this description, \langle constructor \rangle refers to the name of the record ('point' in the example above) and \langle name \rangle to the name of an argument (field).

- \textit{default}._\langle constructor \rangle(-Record)
  Create a new record where all fields have their default values. This is the same as make._\langle constructor \rangle([], Record).

- \textit{make}._\langle constructor \rangle(+Fields, -Record)
  Create a new record where specified fields have the specified values and remaining fields have their default value. Each field is specified as a term \langle name \rangle(\langle value \rangle). See example in the introduction.

- \textit{make}._\langle constructor \rangle(+Fields, -Record, -RestFields)
  Same as \textit{make}._\langle constructor \rangle/2, but named fields that do not appear in Record are returned in RestFields. This predicate is motivated by option-list processing. See library option.

- \langle constructor \rangle._\langle name \rangle(Record, Value)
  Unify Value with argument in Record named \langle name \rangle.\footnote{Note this is not called ‘get’ as it performs unification and can perfectly well instantiate the argument.}

- \textit{set}._\langle name \rangle.of._\langle constructor \rangle(+Value, +OldRecord, -NewRecord)
  Replace the value for \langle name \rangle in OldRecord by Value and unify the result with NewRecord.

- \textit{set}._\langle name \rangle.of._\langle constructor \rangle(+Value, !Record)
  Destructively replace the argument \langle name \rangle in Record by Value based on setarg/3. Use with care.

- \textit{nb_set}._\langle name \rangle.of._\langle constructor \rangle(+Value, !Record)
  As above, but using non-backtrackable assignment based on nb_setarg/3. Use with extreme care.
• set\langleconstructor\rangle fields(+Fields, +Record0, -Record)
  Set multiple fields using the same syntax as make\langleconstructor\rangle/2, but starting with Record0 rather than the default record.

• set\langleconstructor\rangle fields(+Fields, +Record0, -Record, -RestFields)
  Similar to set\langleconstructor\rangle.fields/4, but fields not defined by \langleconstructor\rangle are returned in RestFields.

• set\langleconstructor\rangle field(+Field, +Record0, -Record)
  Set a single field specified as a term \langlename\rangle\langlevalue\rangle.

record(+Spec)
  The construct :- record Spec, ... is used to define access to named fields in a compound. It is subject to term-expansion (see expand_term/2) and cannot be called as a predicate. See section A.20 for details.

A.21 registry: Manipulating the Windows registry

The registry is only available on the MS-Windows version of SWI-Prolog. It loads the foreign extension plregtry.dll, providing the predicates described below. This library only makes the most common operations on the registry available through the Prolog user. The underlying DLL provides a more complete coverage of the Windows registry API. Please consult the sources in pl/src/win32/foreign/plregtry.c for further details.

In all these predicates, Path refers to a '/' separated path into the registry. This is not an atom containing '/'-characters as used for filenames, but a term using the functor //2. Windows defines the following roots for the registry: classes_root, current_user, local_machine and users

registry_get_key(+Path, -Value)
  Get the principal (default) value associated to this key. Fails silently if the key does not exist.

registry_get_key(+Path, +Name, -Value)
  Get a named value associated to this key.

registry_set_key(+Path, +Value)
  Set the principal (default) value of this key. Creates (a path to) the key if this does not already exist.

registry_set_key(+Path, +Name, +Value)
  Associated a named value to this key. Creates (a path to) the key if this does not already exist.

registry_delete_key(+Path)
  Delete the indicated key.

shell_register_file_type(+Ext, +Type, +Name, +OpenAction)
  Register a file-type. Ext is the extension to associate. Type is the type name, often something link prolog.type. Name is the name visible in the Windows file-type browser. Finally, OpenAction defines the action to execute when a file with this extension is opened in the Windows explorer.
A.22. **SIMPLEX: SOLVE LINEAR PROGRAMMING PROBLEMS**

shell_register_dde(+Type, +Action, +Service, +Topic, +Command, +IfNotRunning)

Associate DDE actions to a type. Type is the same type as used for the 2nd argument of shell_register_file_type/4. Action is the a action to perform, Service and Topic specify the DDE topic to address and Command is the command to execute on this topic. Finally, IfNotRunning defines the command to execute if the required DDE server is not present.

shell_register_prolog(+Ext)

Default registration of SWI-Prolog, which is invoked as part of the initialisation process on Windows systems. As the source also explains the above predicates, it is given as an example:

```prolog
shell_register_prolog(Ext) :-
    current_prolog_flag(argv, [Me|_]),
    concat_atom(["", Me, "" ""]], OpenCommand),
    shell_register_file_type(Ext, 'prolog.type', 'Prolog Source', OpenCommand),
    shell_register_dde('prolog.type', consult, prolog, control, 'consult(''%1'')', Me),
    shell_register_dde('prolog.type', edit, prolog, control, 'edit(''%1'')', Me).
```

A.22 **simplex: Solve linear programming problems**

Author: Markus Triska

A linear programming problem consists of a set of (linear) constraints, a number of variables and a linear objective function. The goal is to assign values to the variables so as to maximize (or minimize) the value of the objective function while satisfying all constraints.

Many optimization problems can be modeled in this way. Consider having a knapsack with fixed capacity C, and a number of items with sizes s(i) and values v(i). The goal is to put as many items as possible in the knapsack (not exceeding its capacity) while maximizing the sum of their values.

As another example, suppose you are given a set of coins with certain values, and you are to find the minimum number of coins such that their values sum up to a fixed amount. Instances of these problems are solved below.

The simplex module provides the following predicates:

**assignment(+Cost, -Assignment)**

Cost is a list of lists representing the quadratic cost matrix, where element (i,j) denotes the cost of assigning entity i to entity j. An assignment with minimal cost is computed and unified with Assignment as a list of lists, representing an adjacency matrix.

**constraint(+Constraint, +S0, -S)**

Adds a linear or integrality constraint to the linear program corresponding to state S0. A linear constraint is of the form "Left Op C", where "Left" is a list of Coefficient*Variable terms (variables in the context of linear programs can be atoms or compound terms) and C is a non-negative numeric constant. The list represents the sum of its elements. Op can
be =, =¡ or =¿. The coefficient "1" can be omitted. An integrality constraint is of the form integral(Variable) and constrains Variable to an integral value.

\[\text{constraint}(\text{+Name}, \text{+Constraint}, \text{+S0}, \text{-S})\]

Like constraint/3, and attaches the name Name (an atom or compound term) to the new constraint.

\[\text{constraint}\_\text{add}(\text{+Name}, \text{+Left}, \text{+S0}, \text{-S})\]

*Left* is a list of Coefficient*Variable* terms. The terms are added to the left-hand side of the constraint named Name. S is unified with the resulting state.

\[\text{gen}\_\text{state}(\text{-State})\]

Generates an initial state corresponding to an empty linear program.

\[\text{maximize}(\text{+Objective}, \text{+S0}, \text{-S})\]

Maximizes the objective function, stated as a list of "Coefficient*Variable" terms that represents the sum of its elements, with respect to the linear program corresponding to state S0. S is unified with an internal representation of the solved instance.

\[\text{minimize}(\text{+Objective}, \text{+S0}, \text{-S})\]

Analogous to maximize/3.

\[\text{objective}(\text{+State}, \text{-Objective})\]

Unifies Objective with the result of the objective function at the obtained extremum. State must correspond to a solved instance.

\[\text{shadow}\_\text{price}(\text{+State}, \text{+Name}, \text{-Value})\]

Unifies Value with the shadow price corresponding to the linear constraint whose name is Name. State must correspond to a solved instance.

\[\text{transportation}(\text{+Supplies}, \text{+Demands}, \text{+Costs}, \text{-Transport})\]

Supplies and Demands are both lists of positive numbers. Their respective sums must be equal. Costs is a list of lists representing the cost matrix, where an entry (i,j) denotes the cost of transporting one unit from i to j. A transportation plan having minimum cost is computed and unified with Transport in the form of a list of lists that represents the transportation matrix, where element (i,j) denotes how many units to ship from i to j.

\[\text{variable}\_\text{value}(\text{+State}, \text{+Variable}, \text{-Value})\]

Value is unified with the value obtained for Variable. State must correspond to a solved instance.

All numeric quantities are converted to rationals via rationalize/1, and rational arithmetic is used throughout solving linear programs. In the current implementation, all variables are implicitly constrained to be non-negative. This may change in future versions, and non-negativity constraints should therefore be stated explicitly.

### A.22.1 Example 1

This is the "radiation therapy" example, taken from "Introduction to Operations Research" by Hillier and Lieberman. DCG notation is used to implicitly thread the state through posting the constraints:
A.22. **SIMPLEX: SOLVE LINEAR PROGRAMMING PROBLEMS**

:- use_module(library(simplex)).

post_constraints -->
  constraint([0.3*x1, 0.1*x2] <= 2.7),
  constraint([0.5*x1, 0.5*x2] = 6),
  constraint([0.6*x1, 0.4*x2] >= 6),
  constraint([x1] >= 0),
  constraint([x2] >= 0).

radiation(S) :-
  gen_state(S0),
  post_constraints(S0, S1),
  minimize([0.4*x1, 0.5*x2], S1, S).

An example query:

?- radiation(S), variable_value(S, x1, Val1), variable_value(S, x2, Val2).

Val1 = 15 rdiv 2
Val2 = 9 rdiv 2 ;

A.22.2 Example 2

Here is an instance of the knapsack problem described above, where C = 8, and we have two types of items: One item with value 7 and size 6, and 2 items each having size 4 and value 4. We introduce two variables, x(1) and x(2) that denote how many items to take of each type.

knapsack_constrain(S) :-
  gen_state(S0),
  constraint([6*x(1), 4*x(2)] <= 8, S0, S1),
  constraint([x(1)] <= 1, S1, S2),
  constraint([x(2)] <= 2, S2, S).

knapsack(S) :-
  knapsack_constrain(S0),
  maximize([7*x(1), 4*x(2)], S0, S).

An example query yields:

?- knapsack(S), variable_value(S, x(1), X1), variable_value(S, x(2), X2).

X1 = 1
X2 = 1 rdiv 2 ;

That is, we are to take the one item of the first type, and half of one of the items of the other type to maximize the total value of items in the knapsack.

If items can not be split, integrality constraints have to be imposed:
APPENDIX A. THE SWI-PROLOG LIBRARY

knapsack_integral(S) :-
    knapsack_constrain(S0),
    constraint(integral(x(1)), S0, S1),
    constraint(integral(x(2)), S1, S2),
    maximize([7*x(1), 4*x(2)], S2, S).

Now the result is different:

?- knapsack_integral(S), variable_value(S, x(1), X1), variable_value(S, x(2), X2).

X1 = 0
X2 = 2

That is, we are to take only the two items of the second type. Notice in particular that always choosing the remaining item with best performance (ratio of value to size) that still fits in the knapsack does not necessarily yield an optimal solution in the presence of integrality constraints.

A.22.3 Example 3

We are given 3 coins each worth 1, 20 coins each worth 5, and 10 coins each worth 20 units of money. The task is to find a minimal number of these coins that amount to 111 units of money. We introduce variables c(1), c(5) and c(20) denoting how many coins to take of the respective type:

coins -->
    constraint([c(1), 5*c(5), 20*c(20)] = 111),
    constraint([c(1)] =< 3),
    constraint([c(5)] =< 20),
    constraint([c(20)] =< 10),
    constraint([c(1)] >= 0),
    constraint([c(5)] >= 0),
    constraint([c(20)] >= 0),
    constraint(integral(c(1))),
    constraint(integral(c(5))),
    constraint(integral(c(20))),
    minimize([c(1), c(5), c(20)]).

coins(S) :-
    gen_state(S0),
    coins(S0, S).

An example query:

?- coins(S), variable_value(S, c(1), C1), variable_value(S, c(5), C5), variable_value(S, c(20), C20).

C1 = 1
C5 = 2
C20 = 5
A.23 thread_pool.pl – Resource bounded thread management

The module library(thread_pool) manages threads in pools. A pool defines properties of its member threads and the maximum number of threads that can coexist in the pool. The call thread_create_in_pool/4 allocates a thread in the pool, just like thread_create/3. If the pool is fully allocated it can be asked to wait or raise an error.

The library has been designed to deal with server application that recieve a variety of requests, such as HTTP servers. Simply starting a thread for each request is a bit too simple minded for such servers:

- Creating many CPU intensive threads often leads to a slow-down rather than a speedup.
- Creating many memory intensive threads may exhaust resources
- Tasks that require little CPU and memory but take long waiting for external resources can run many threads.

Using this library, one can define a pool for each set of tasks with comparable characteristics and create threads in this pool. Unlike the worker-pool model, threads are not started immediately. Depending on the design, both approaches can be attractive.

The library is implemented by means of a manager thread with the fixed thread id \_thread_pool_manager. All state is maintained in this manager thread, which receives and processes requests to create and destroy pools, create threads in a pool and handle messages from terminated threads. Thread pools are not saved in a saved state and must therefore be recreated using the initialization/1 directive or otherwise during startup of the application.

**thread_pool_create(+Pool, +Size, +Options)**

Create a pool of threads. A pool of threads is a declaration for creating threads with shared properties (stack sizes) and a limited number of threads. Threads are created using thread_create_in_pool/4. If all threads in the pool are in use, the behaviour depends on the wait option of thread_create_in_pool/4 and the backlog option described below. Options are passed to thread_create/3, except for

backlog(+MaxBackLog)

Maximum number of requests that can be suspended. Default is infinite. Otherwise it must be a non-negative integer. Using backlog(0) will never delay thread creation for this pool.

The pooling mechanism does not interact with the detached state of a thread. Threads can be created but detached and normal and must be joined using thread_join/2 if they are not detached.

**thread_pool_destroy(+Name)**

Destroy the thread pool named Name.
Errors  existence_error(thread_pool, Name).

current_thread_pool(?Name) \[nondet\]
True if Name refers to a defined thread pool.

thread_pool_property(?Name, ?Property) \[nondet\]
True if Property is a property of thread pool Name. Defined properties are:

  options(Options)
  Thread creation options for this pool
  free(Size)
  Number of free slots on this pool
  backlog(Size)
  Number of delayed thread creations on this pool

thread_create_in_pool(+Pool, -Goal, -Id, +Options) \[det\]
Create a thread in Pool. Options overrule default thread creation options associated to the pool. In addition, the following option is defined:

  wait(+Boolean)
  If true (default) and the pool is full, wait until a member of the pool completes. If false, throw a resource_error.

Errors  resource_error(threads_in_pool(Pool)) is raised if wait is false or the backlog limit has been reached.

A.24  ugraphs: Unweighted Graphs

Authors: Richard O’Keefe & Vitor Santos Costa

Implementation and documentation are copied from YAP 5.0.1. The ugraph library is based on code originally written by Richard O’Keefe. The code was then extended to be compatible with the SICStus Prolog ugraphs library. Code and documentation have been cleaned and style has been changed to be more in line with the rest of SWI-Prolog.

The ugraphs library was originally released in the public domain. YAP is covered by the Perl artistic license, which does not imply further restrictions on the SWI-Prolog LGPL license.

The routines assume directed graphs, undirected graphs may be implemented by using two edges. Originally graphs where represented in two formats. The SICStus library and this version of ugraphs.pl only uses the S-representation. The S-representation of a graph is a list of (vertex-neighbors) pairs, where the pairs are in standard order (as produced by keysort) and the neighbors of each vertex are also in standard order (as produced by sort). This form is convenient for many calculations. Each vertex appears in the S-representation, also if it has no neighbors.

vertices_edges_to_ugraph(+Vertices, +Edges, -Graph)
Given a graph with a set of Vertices and a set of Edges, Graph must unify with the corresponding S-representation. Note that the vertices without edges will appear in Vertices but not in Edges. Moreover, it is sufficient for a vertex to appear in Edges.
?- vertices_edges_to_ugraph([], [1-3, 2-4, 4-5, 1-5], L).
L = [1-[3,5], 2-[4], 3-[], 4-[5], 5-[]]

In this case all vertices are defined implicitly. The next example shows three unconnected vertices:

?- vertices_edges_to_ugraph([6, 7, 8], [1-3, 2-4, 4-5, 1-5], L).
L = [1-[3,5], 2-[4], 3-[], 4-[5], 5-[], 6-[], 7-[], 8-[]]

vertices(+Graph, -Vertices)
Unify Vertices with all vertices appearing in graph Graph. Example:

?- vertices([1-[3,5], 2-[4], 3-[], 4-[5], 5-[]], L).
L = [1, 2, 3, 4, 5]

edges(+Graph, -Edges)
Unify Edges with all edges appearing in Graph. In the next example:

?- edges([1-[3,5], 2-[4], 3-[], 4-[5], 5-[]], L).
L = [1-3, 1-5, 2-4, 4-5]

add_vertices(+Graph, +Vertices, -NewGraph)
Unify NewGraph with a new graph obtained by adding the list of Vertices to the Graph. Example:

?- add_vertices([1-[3,5], 2-[4], 3-[], 4-[5], 5-[]], [0, 1, 2, 9], NG).
NG = [0-[], 1-[3,5], 2-[], 9-[]]

del_vertices(+Graph, +Vertices, -NewGraph)
Unify NewGraph with a new graph obtained by deleting the list of Vertices and all the edges that start from or go to a vertex in Vertices to the Graph. Example:

?- del_vertices([2,1],
[1-[3,5], 2-[4], 3-[], 4-[5], 5-[], 6-[], 7-[2,6], 8-[]], NL).
NL = [3-[], 4-[5], 5-[], 6-[], 7-[6], 8-[]]

add_edges(+Graph, +Edges, -NewGraph)
Unify NewGraph with a new graph obtained by adding the list of edges Edges to the graph Graph. Example:

?- add_edges([1-[3,5], 2-[4], 3-[], 4-[5], 5-[], 6-[], 7-[], 8-[]],
[1-6, 2-3, 3-2, 5-7, 3-2, 4-5], NL).
NL = [1-[3,5,6], 2-[3,4], 3-[2], 4-[5], 5-[7], 6-[], 7-[], 8-[]]
del_edges(+Graph, +Edges, -NewGraph)
Unify NewGraph with a new graph obtained by removing the list of Edges from the Graph. Notice that no vertices are deleted. In the next example:

?- del_edges([1-[3,5],2-[4],3-[],4-[5],5-[],6-[],7-[],8-[]),
       [1-6,2-3,3-2,5-7,3-2,4-5,1-3],
       NL).
NL = [1-[5],2-[4],3-[],4-[],5-[],6-[],7-[],8-[]]

transpose(+Graph, -NewGraph)
Unify NewGraph with a new graph obtained from Graph by replacing all edges of the form V1-V2 by edges of the form V2-V1. The cost is $O(|V|^2)$. Notice that an undirected graph is its own transpose. Example:

?- transpose([1-[3,5],2-[4],3-[],4-[5],5-[],6-[],7-[],8-[]], NL).
NL = [1-[],2-[],3-[1],4-[2],5-[1,4],6-[],7-[],8-[]]

eighbours(+Vertex, +Graph, -Vertices)
Unify Vertices with the list of neighbours of vertex Vertex in Graph. Example:

?- neighbours(4,[1-[3,5],2-[4],3-[],
      4-[1,2,7,5],5-[],6-[],7-[],8-[]], NL).
NL = [1,2,7,5]

neighbors(+Vertex, +Graph, -Vertices)
American version of neighbours/3.

complement(+Graph, -NewGraph)
Unify NewGraph with the graph complementary to Graph. Example:

?- complement([1-[3,5],2-[4],3-[],
        4-[1,2,7,5],5-[],6-[],7-[],8-[]], NL).
NL = [1-[2,4,6,7,8],2-[1,3,5,6,7,8],3-[1,2,4,5,6,7,8],
      4-[3,5,6,8],5-[1,2,3,4,6,7,8],6-[1,2,3,4,5,7,8],
      7-[1,2,3,4,5,6,8],8-[1,2,3,4,5,6,7]]

compose(+LeftGraph, +RightGraph, -NewGraph)
Compose, by connecting the drains of LeftGraph to the sources of RightGraph. Example:

?- compose([1-[2],2-[3]], [2-[4],3-[1,2,4]], L).
L = [1-[4], 2-[1,2,4], 3-[]]

ugraph_union(+Graph1, +Graph2, -NewGraph)
NewGraph is the union of Graph1 and Graph2. Example:
?- ugraph_union([1-[2], 2-[3]), [2-[4], 3-[1,2,4]], L).
L = [1-[2], 2-[3,4], 3-[1,2,4]]

top_sort(+Graph, -Sort)
Generate the set of nodes Sort as a topological sorting of graph Graph, if one is possible. A topological sort is possible if the graph is connected and acyclic. In the example we show how topological sorting works for a linear graph:

?- top_sort([1-[2], 2-[3], 3-[]], L).
L = [1, 2, 3]

top_sort(+Graph, -Sort0, -Sort)
Generate the difference list Sort-Sort0 as a topological sorting of graph Graph, if one is possible.

transitive_closure(+Graph, -Closure)
Generate the graph Closure as the transitive closure of graph Graph. Example:

?- transitive_closure([1-[2,3], 2-[4,5], 4-[6]], L).
L = [1-[2,3,4,5,6], 2-[4,5,6], 4-[6]]

reachable(+Vertex, +Graph, -Vertices)
Unify Vertices with the set of all vertices in graph Graph that are reachable from Vertex. Example:

?- reachable(1, [1-[3,5], 2-[4], 3-[], 4-[5], 5-[]], V).
V = [1, 3, 5]

A.25 url.pl – Analysing and constructing URL

author
- Jan Wielemaker
- Lukas Faulstich

This library deals with the analysis and construction of a URL, Universal Resource Locator. URL is the basis for communicating locations of resources (data) on the web. A URL consists of a protocol identifier (e.g. HTTP, FTP, and a protocol-specific syntax further defining the location. URLs are standardized in RFC-1738.

The implementation in this library covers only a small portion of the defined protocols. Though the initial implementation followed RFC-1738 strictly, the current is more relaxed to deal with frequent violations of the standard encountered in practical use.

global_url(+URL, +Base, -Global) [det]
Translate a possibly relative URL into an absolute one.
Errors  syntax_error(illegal_url) if URL is not legal.

**is_absolute_url(+URL)**

True if URL is an absolute URL. That is, a URL that starts with a protocol identifier.

**http_location(?Parts, ?Location)**

Construct or analyze an HTTP location. This is similar to `parse_url/2`, but only deals with the location part of an HTTP URL. That is, the path, search and fragment specifiers. In the HTTP protocol, the first line of a message is

```
<Action> <Location> HTTP/<version>
```

Parameters

<table>
<thead>
<tr>
<th>Location</th>
<th>Atom or list of character codes.</th>
</tr>
</thead>
</table>

**parse_url(+URL, -Attributes)**

Construct or analyse a URL. URL is an atom holding a URL or a variable. Parts is a list of components. Each component is of the format Name=Value. Defined components are:

**protocol(Protocol)**

The used protocol. This is, after the optional `url:`, an identifier separated from the remainder of the URL using `:`. `parse_url/2` assumes the `http` protocol if no protocol is specified and the URL can be parsed as a valid HTTP url. In addition to the RFC-1738 specified protocols, the `file` protocol is supported as well.

**host(Host)**

Host-name or IP-address on which the resource is located. Supported by all network-based protocols.

**port(Port)**

Integer port-number to access on the `\arg{Host}`. This only appears if the port is explicitly specified in the URL. Implicit default ports (e.g. 80 for HTTP) do not appear in the part-list.

**path(Path)**

(File-) path addressed by the URL. This is supported for the `ftp`, `http` and `file` protocols. If no path appears, the library generates the path `/`

**search(ListOfNameValue)**

Search-specification of HTTP URL. This is the part after the `?`, normally used to transfer data from HTML forms that use the `GET` protocol. In the URL it consists of a www-form-encoded list of Name=Value pairs. This is mapped to a list of Prolog Name=Value terms with decoded names and values.

**fragment(Fragment)**

Fragment specification of HTTP URL. This is the part after the `#` character.

The example below illustrates the all this for an HTTP URL.

P = [ protocol(http),
     host('swi.psy.uva.nl'),
     fragment(x),
     search([ msg = 'Hello World!' ]),
     path('/message.cgi') ]

By instantiating the parts-list this predicate can be used to create a URL.

www_form_encode(+Value, -XWWWFormEncoded) [det]
www_form_encode(-Value, +XWWWFormEncoded) [det]
En/Decode between native value and application/x-www-form-encoded. Maps space to +, keeps alnum, maps anything else to %XX and newlines to %OD%OA. When decoding, newlines appear as a single newline (10) character.

url_iri(+Encoded, -Decoded) [det]
url_iri(-Encoded, +Decoded) [det]
Convert between a URL, encoding in US-ASCII and an IRI. An IRI is a fully expanded Unicode string. Unicode strings are first encoded into UTF-8, after which %-encoding takes place.

parse_url_search(?Spec, ?Fields:list(Name=Value)) [det]
Construct or analyze an HTTP search specification. This deals with form data using the MIME-type =application/x-www-form-urlencoded= as used in HTTP GET requests.

file_name_to_url(+File, -URL) [det]
file_name_to_url(-File, +URL) [semidet]
Translate between a filename and a file: // URL.

To be done Current implementation does not deal with paths that need special encoding.
This appendix describes a number of predicates which enable the Prolog user to inspect the Prolog environment and manipulate (or even redefine) the debugger. They can be used as entry points for experiments with debugging tools for Prolog. The predicates described here should be handled with some care as it is easy to corrupt the consistency of the Prolog system by misusing them.

B.1 Examining the Environment Stack

prolog_current_frame(-Frame)
Unify Frame with an integer providing a reference to the parent of the current local stack frame. A pointer to the current local frame cannot be provided as the predicate succeeds deterministically and therefore its frame is destroyed immediately after succeeding.

prolog_frame_attribute(+Frame, +Key, -Value)
Obtain information about the local stack frame Frame. Frame is a frame reference as obtained through prolog.current_frame/1, prolog.trace_interception/4 or this predicate. The key values are described below.

  alternative
  Value is unified with an integer reference to the local stack frame in which execution is resumed if the goal associated with Frame fails. Fails if the frame has no alternative frame.

  has_alternatives
  Value is unified with true if Frame still is a candidate for backtracking. false otherwise.

  goal
  Value is unified with the goal associated with Frame. If the definition module of the active predicate is not user the goal is represented as ⟨module⟩: ⟨goal⟩. Do not instantiate variables in this goal unless you know what you are doing! Note that the returned term may contain references to the frame and should be discarded before the frame terminates.¹

  parent_goal
  If Value is instantiated to a callable term, find a frame executing the predicate described by Value and unify the arguments of Value to the goal arguments associated with the frame. This is intended to check the current execution context. The user must ensure the checked parent goal is not removed from the stack due to last-call optimisation and be aware of the slow operation on deeply nested calls.

¹The returned term is actually an illegal Prolog term that may hold references from the global- to the local stack to preserve the variable names.
predicate_indicator

Similar to goal, but only returning the \([\langle\text{module}\rangle:\langle\text{name}\rangle/\langle\text{arity}\rangle]\) term describing the term, not the actual arguments. It avoids creating an illegal term as goal and is used by the library prolog_stack.

clause

Value is unified with a reference to the currently running clause. Fails if the current goal is associated with a foreign (C) defined predicate. See also nth_clause/3 and clause_property/2.

level

Value is unified with the recursion level of Frame. The top level frame is at level ‘0’.

parent

Value is unified with an integer reference to the parent local stack frame of Frame. Fails if Frame is the top frame.

collection_module

Value is unified with the name of the context module of the environment.

argument\( (N) \)

Value is unified with the \(N\)-th slot of the frame. Argument 1 is the first argument of the goal. Arguments above the arity refer to local variables. Fails silently if \(N\) is out of range.

prolog_choice_attribute\((ChoicePoint, +Key, -Value)\)

Extract attributes of a choice-point. ChoicePoint is a reference to a choice-point as passed to prolog_trace_interception/4 on the 3-th argument. Key specifies the requested information:

parent

Requests a reference to the first older choice-point.

frame

Requests a reference to the frame to which the choice-point refers.

type

Requests the type. Defined values are clause (the goal has alternative clauses), foreign (non-deterministic foreign predicate), jump (clause internal choice-point), top (first dummy choice-point), catch (catch/3 to allow for undo), debug (help the debugger), or none (has been deleted).

This predicate is used for the graphical debugger to show the choice-point stack.
deterministic(-Boolean)
Unifies its argument with true if no choicepoint exists that is more recent than the entry of the clause in which it appears. There are few realistic situations for using this predicate. It is used by the prolog/0 toplevel to check whether Prolog should prompt the user for alternatives. Similar results can be achieved in a more portable fashion using call_cleanup/2.

B.2 Intercepting the Tracer

prolog_trace_interception(+Port, +Frame, +Choice, -Action)
Dynamic predicate, normally not defined. This predicate is called from the SWI-Prolog debugger just before it would show a port. If this predicate succeeds the debugger assumes the trace action has been taken care of and continues execution as described by Action. Otherwise the normal Prolog debugger actions are performed.

Port denotes the reason to activate the tracer (‘port’ in the 4/5-port, but with some additions:

call
Normal entry through the call-port of the 4-port debugger.

redo
Normal entry through the call-port of the 4-port debugger. The redo port signals resuming a predicate to generate alternative solutions.

unify
The unify-port represents the neck instruction, signalling the end of the head-matching process. This port is normally invisible. See leash/1 and visible/1.

exit
The exit-port signals the goal is proved. It is possible for the goal to have alternative. See prolog_frame_attribute/3 to examine the goal-stack.

fail
The fail-port signals final failure of the goal.

exception(Except)
An exception is raised and still pending. This port is activated on each parent frame of the frame generating the exception until the exception is caught or the user restarts normal computation using retry. Except is the pending exception-term.

break(PC)
A break instruction is executed. PC is program counter. This port is used by the graphical debugger.

cut_call(PC)
A cut is encountered at PC. This port is used by the graphical debugger to visualise the effect of the cut.

cut_exit(PC)
A cut has been executed. See cut_call(PC) for more information.

Frame is a reference to the current local stack frame, which can be examined using prolog_frame_attribute/3. Choice is a reference to the last choice-point and can be examined using prolog_choice_attribute/3. Action should be unified with one of the
Atoms `continue` (just continue execution), `retry` (retry the current goal) or `fail` (force the current goal to fail). Leaving it a variable is identical to `continue`.

Together with the predicates described in section 4.38 and the other predicates of this chapter this predicate enables the Prolog user to define a complete new debugger in Prolog. Besides this it enables the Prolog programmer monitor the execution of a program. The example below records all goals trapped by the tracer in the database.

```prolog
prolog_trace_interception(Port, Frame, _PC, continue) :-
    prolog_frame_attribute(Frame, goal, Goal),
    prolog_frame_attribute(Frame, level, Level),
    recordz(trace, trace(Port, Level, Goal)).
```

To trace the execution of ‘go’ this way the following query should be given:

```prolog
?- trace, go, notrace.
```

**prolog_skip_level(-Old, +New)**

Unify `Old` with the old value of ‘skip level’ and than set this level according to `New`. New is an integer, or the special atom very_deep (meaning don’t skip). The ‘skip level’ is a global variable of the Prolog system that disables the debugger on all recursion levels deeper than the level of the variable. Used to implement the trace options ‘skip’ (sets skip level to the level of the frame) and ‘up’ (sets skip level to the level of the parent frame (i.e., the level of this frame minus 1).

**B.3 Adding context to errors: prolog_exception_hook**

The hook `prolog_exception_hook/4` has been introduced in SWI-Prolog 5.6.5 to provide dedicated exception handling facilities for application frameworks. For example non-interactive server applications that wish to provide extensive context for exceptions for offline debugging.

**prolog_exception_hook(+ExceptionIn, -ExceptionOut, +Frame, +CatcherFrame)**

This hook predicate, if defined in the module `user`, is between raising an exception and handling it. It is intended to allow a program adding additional context to an exception to simplify diagnosing the problem. `ExceptionIn` is the exception term as raised by `throw/1` or one of the built-in predicates. The output argument `ExceptionOut` describes the exception that is actually raised. `Frame` is the innermost frame. See `prolog_frame_attribute/3` and the library `prolog_stack` for getting information from this. `CatcherFrame` is a reference to the frame calling the matching `catch/3` or none of the exception is not caught.

The hook is run in ‘nodebug’ mode. If it succeeds `ExceptionOut` is considered the current exception. If it fails, `ExceptionIn` is used for further processing. The hook is never called recursively. The hook is not allowed to modify `ExceptionOut` in such as way that it no longer unifies with the catching frame.

Typically, `prolog_exception_hook/4` is used to fill the second argument of `error(Formal, Context)` exceptions. `Formal` is defined by the ISO standard, while SWI-Prolog defines `Context` as a term `context(Location, Message)`. `Location` is bound to a term...
⟨name⟩/⟨arity⟩ by the kernel. This hook can be used to add more information on the calling context, such as a full stack trace.

Applications that use exceptions as part of normal processing must do a quick test of the environment before starting expensive gathering information on the state of the program. The hook can call trace/0 to enter trace mode immediately. For example imagine an application performing an unwanted division by zero while all other errors are expected and handled. We can force the debugger using the hook definition below. Run the program in debug mode (see debug/0) to preserve as much as possible of the error context.

user:prolog_exception_hook(error(evaluation_error(zero_divisor), _), _, _, _) :-
                trace, fail.

B.4 Hooks using the exception predicate

This section describes the predicate exception/3, which can be defined by the user in the module user as a multifile predicate. Unlike the name suggests, this is actually a hook predicate that has no relation to Prolog exceptions as defined by the ISO predicates catch/3 and throw/1.

The predicate exception/3 is called by the kernel on a couple of events, allowing the user to ‘fix’ errors just in time events. The mechanism allows for lazy creation of objects such as predicates.

exception(+Exception, +Context, -Action)
Dynamic predicate, normally not defined. Called by the Prolog system on run-time exceptions that can be repaired ‘just in time’. The values for Exception are described below. See also catch/3 and throw/1.

If this hook predicate succeeds it must instantiate the Action argument to the atom fail to make the operation fail silently, retry to tell Prolog to retry the operation or error to make the system generate an exception. The action retry only makes sense if this hook modified the environment such that the operation can now succeed without error.

undefined_predicate
Context is instantiated to a term Name/Arity. Name refers to the name and Arity to the arity of the undefined predicate. If the definition module of the predicate is not user, Context will be of the form <Module>:⟨Name⟩/⟨Arity⟩. If the predicate fails Prolog will generate an existence_error exception.

undefined_global_variable
Context is instantiated to the name of the missing global variable. The hook must call nb_setval/2 or b_setval/2 before returning with the action retry.

B.5 Hooks for integrating libraries

Some libraries realise an entirely new programming paradigm on top of Prolog. An example is XPCE which adds an object-system to Prolog as well as an extensive set of graphical primitives. SWI-Prolog provides several hooks to improve the integration of such libraries. See also section 4.4 for editing hooks and section 4.9.3 for hooking into the message system.
**B.6. HOOKS FOR LOADING FILES**

---

**prolog_list_goal(:Goal)**
Hook, normally not defined. This hook is called by the ‘L’ command of the tracer in the module user to list the currently called predicate. This hook may be defined to list only relevant clauses of the indicated Goal and/or show the actual source-code in an editor. See also portray/1 and multifile/1.

**prolog:debug_control_hook(:Action)**
Hook for the debugger-control predicates that allows the creator of more high-level programming languages to use the common front-end predicates to control de debugger. For example, XPCE uses these hooks to allow for spying methods rather then predicates. **Action** is one of:

- **spy(Spec)**
  Hook in spy/1. If the hook succeeds spy/1 takes no further action.

- **nospy(Spec)**
  Hook in nospy/1. If the hook succeeds spy/1 takes no further action. If spy/1 is hooked, it is advised to place a complementary hook for nospy/1.

- **nospyall**
  Hook in nospyall/0. Should remove all spy-points. This hook is called in a failure-driven loop.

- **debugging**
  Hook in debugging/0. It can be used in two ways. It can report the status of the additional debug-points controlled by the above hooks and fail to let the system report the others or it succeed, overruling the entire behaviour of debugging/0.

**prolog:help_hook(+Action)**
Hook into help/0 and help/1. If the hook succeeds, the built-in actions are not executed. For example, \?- help(picture). is caught by the XPCE help-hook to give help on the class picture. Defined actions are:

- **help**
  User entered plain help/0 to give default help. The default performs help(help/1), giving help on help.

- **help(What)**
  Hook in help/1 on the topic What.

- **apropos(What)**
  Hook in apropos/1 on the topic What.

---

**B.6 Hooks for loading files**

All loading of source-files is achieved by load_files/2. The hook prolog_load_file/2 can be used to load Prolog code from non-files or even load entirely different information, such as foreign files.

**prolog_load_file(+Spec, +Options)**
Load a single object. If this call succeeds, load_files/2 assumes the action has been taken
care of. This hook is only called if Options does not contain the \texttt{stream(Input)} option. The hook must be defined in the module \texttt{user}.

The \texttt{http_load} provides an example, loading Prolog sources directly from an HTTP server.

\begin{verbatim}
prolog:comment_hook(+Comments, +Pos, +Term)
This hook allows for processing —structured— comments encountered by the compiler. The reader collects all comments found from the current position to the end of the next term. It calls this hook providing a list of Position-Comment in Comments, the start-position of the next term in Pos and the next term itself in Term. All positions are stream-position terms. This hook is exploited by the documentation system. See \texttt{stream_position_data/3}. See also \texttt{read_term/3}.
\end{verbatim}

### B.7 Readline Interaction

The following predicates are available if SWI-Prolog is linked to the GNU readline library. This is by default the case on non-Windows installations and indicated by the Prolog flag \texttt{readline}.\footnote{\texttt{plwin.exe} uses its own history system and does not support these predicates.} See also \texttt{readline(3)}

\begin{verbatim}
rl_read_init_file(+File)
Read a readline initialisation file. Readline by default reads \texttt{~/.inputrc}. This predicate may be used to read alternative readline initialisation files.

rl_add_history(+Line)
Add a line to the Control-P/Control-N history system of the readline library.

rl_write_history(+FileName)
Write current history to \texttt{FileName}. Can be used from \texttt{at_halt/1} to save the history.

rl_read_history(+FileName)
Read history from \texttt{FileName}, appending to the current history.
\end{verbatim}
Compatibility with other Prolog dialects

This chapter explains issues for writing portable Prolog programs. It was started after discussion with Vitor Santos Costa, the leading developer of YAP Prolog\(^1\). YAP and SWI-Prolog have expressed the ambition to enhance the portability beyond the trivial Prolog examples, including complex libraries involving foreign code.

Although it is our aim to enhance compatibility, we are still faced with many incompatibilities between the dialects. As a first step both YAP and SWI will provide some instruments that help developing portable code. A first release of these tools appeared in SWI-Prolog 5.6.43. Some of the facilities are implemented in the base system. Others in the library dialect.pl.

- The Prolog flag `dialect` is an unambiguous and fast way to find out which Prolog dialect executes your program. It has the value `swi` for SWI-Prolog and `yap` on YAP.

- The Prolog flag `version_data` is bound to a term `swi(Major, Minor, Patch, Extra)`

- Conditional compilation using `:- if(Condition) ... :- endif` is supported. See section 4.3.1.

- The predicate `expects_dialect/1` allows for specifying for which Prolog system the code was written.

- The predicates `exists_source/1` and `source_exports/2` can be used to query the library content. The `require/1` directive can be used to get access to predicates without knowing their location.

- The module predicates `use_module/1`, `use_module/2` have been extended with a notion for ‘import-except’ and ‘import-as’. This is particularly useful together with `reexport/1` and `reexport/2` to compose modules from other modules and mapping names.

- Foreign code can expect `_SWI_PROLOG_` when compiled for SWI-Prolog and `_YAP_PROLOG_` when compiled on YAP.

`:- expects_dialect(+Dialect)`

This directive states that the code following the directive is written for the given Prolog `Dialect`. See also `dialect`. The declaration holds until the end of the file in which it appears. The current dialect is available using `prolog_load_context/2`.

The exact behaviour of this predicate is still subject to discussion. Of course, if `Dialect` matches the running dialect the directive has no effect. Otherwise we check for the existence of `library(dialect/Dialect)` and load it if the file is found. Currently, this file has this functionality:

\(^1\)http://yap.sourceforge.net/
APPENDIX C. COMPATIBILITY WITH OTHER PROLOG DIALECTS

- Define system predicates of the requested dialect we do not have.
- Apply `goal Expansion/2` rules that map conflicting predicates to versions emulating the requested dialect. These expansion rules reside in the dialect compatibility module, but are applied if `prolog_load_context(dialect, Dialect)` is active.
- Modify the search path for library directories, putting libraries compatible to the target dialect before the native libraries.
- Setup support for the default filename extension of the dialect.

`exists_source(+Spec)`

Is true if `Spec` exists as a Prolog source. `Spec` uses the same conventions as `load_files/2`. Fails without error if `Spec` cannot be found.

`source_exports(+Spec, +Export)`

Is true if source `Spec` exports `Export`, a predicate indicator. Fails without error otherwise.

### C.1 Some considerations for writing portable code

The traditional way to write portable code is to define custom predicates for all potentially non-portable code and define these separately for all Prolog dialects one wishes to support. Here are some considerations.

- Probably the best reason for this is that it allows to define minimal semantics required by the application for the portability predicates. Such functionality can often be mapped efficiently to the target dialect. Contrary, if code was written for dialect `X`, the defined semantics are those of dialect `X`. Emulating all extreme cases and full error handling compatibility may be tedious and result in a much slower implementation that needed. Take for example `call_cleanup/2`. The SICStus definition is fundamentally different from the SWI definition, but 99% of the applications just want to make calls like below to guarantee `StreamIn` is closed, even if `process/1` misbehaves.

```prolog
call_cleanup(process(StreamIn), close(In))
```

- As a drawback, the code becomes full of `my_call_cleanup`, etc. and every potential portability conflict needs to be abstracted. It is hard for people who have to maintain such code later to grasp the exact semantics of the `my_*` predicates and applications that combine multiple libraries using this compatibility approach are likely to encounter conflicts between the portability layers. A good start is not to use `my_*`, but a prefix derived from the library or application name or names that explain the intended semantics more precisely.

- Another problem is that most code is initially not written with portability in mind. Instead, ports are requested by users or arise from the desire to switch Prolog dialect. Typically, we want to achieve compatibility with the new Prolog dialect with minimal changes, often keeping compatibility with the original dialect(s). This problem is well known from the C/Unix world and we advice anyone to study the philosophy of GNU autoconf, from which we will illustrate some highlights below.
The GNU autoconf suite, known to most people as configure, was an answer to the frustrating life of Unix/C programmers when Unix dialects were about as abundant and poorly standardised as Prolog dialects today. Writing a portable C program can only be achieved using cpp, the C preprocessor. The C preprocessor performs two tasks: macro expansion and conditional compilation. Prolog realises macro expansion through `term_expansion/2` and `goal_expansion/2`. Conditional compilation is achieved using `:- if(Condition)` as explained in section 4.3.1. The situation appears similar.

The important lesson learned from GNU autoconf is that the last resort for conditional compilation to achieve portability is to switch on the platform or dialect. Instead, GNU autoconf allows you to write tests for specific properties of the platform. Most of these are whether or not some function or file is available. Then there are some standard tests for difficult-to-write-portable situations and finally there is a framework that allows you to write arbitrary C programs and check whether they can be compiled and/or whether they show the intended behaviour. Using a separate configure program is needed in C, as you cannot perform C compilation step or run C programs from the C preprocessor. In most Prolog environments we do not need this distinction as the compiler is integrated into the runtime environment and Prolog has excellent reflexion capabilities.

We must learn from the distinction to test for features instead of platform (dialect), as this makes the platform specific code robust for future changes of the dialect. Suppose we need `compare/3` as defined in this manual. The `compare/3` predicate is not part of the ISO standard, but many systems support it and it is not unlikely it will become ISO standard or the intended dialect will start supporting it. GNU autoconf strongly advises to test for the availability:

```prolog
:- if(+current_predicate(_, compare(_,_,_))).
compare(<, Term1, Term2) :-
   Term1 @< Term2, !.
compare(>, Term1, Term2) :-
   Term1 @> Term2, !.
compare(=, Term1, Term2) :-
   Term1 == Term2.
:- endif.
```

This code is much more robust against changes to the intended dialect and, possible at least as important, will provide compatibility to dialects you didn’t even consider porting to right now.

In a more challenging case, the target Prolog has `compare/3`, but the semantics are different. What to do? One option is to write a `my_compare/3` and change all occurrences in the code. Alternatively you can rename calls using `goal_expansion/2` like below. This construct will not only deal with Prolog dialects lacking compare as well as those that only implement it for numeric comparison or have changed the argument order. Of course, writing rock-solid code would require a complete test-suite, but this example will probably cover all Prolog dialects that allow for conditional compilation, have core ISO facilities and provide `goal_expansion/2`, the things we claim a Prolog dialect should have to start writing portable code for it.

```prolog
:- if(+catch(compare(<,a,b), _, fail)).
compare_standard_order(<, Term1, Term2) :-
   Term1 @< Term2, !.
compare_standard_order(>, Term1, Term2) :-
   Term1 @> Term2, !.
```

SWI-Prolog 5.6 Reference Manual
compare_standard_order(=, Term1, Term2) :-
    Term1 == Term2.

goal_expansion(compare(Order, Term1, Term2),
    compare_standard_order(Order, Term1, Term2)).
:- endif.
Glossary of Terms

anonymous [variable]
The variable _ is called the anonymous variable. Multiple occurrences of _ in a single term are not shared.

arguments
Arguments are terms that appear in a compound term. A1 and a2 are the first and second argument of the term myterm(A1, a2).

arity
Argument count (is number of arguments) of a compound term.

assert
Add a clause to a predicate. Clauses can be added at either end of the clause-list of a predicate. See assert/1 and assertz/1.

atom
Textual constant. Used as name for compound terms, to represent constants or text.

backtracking
Searching process used by Prolog. If a predicate offers multiple clauses to solve a goal, they are tried one-by-one until one succeeds. If a subsequent part of the proof is not satisfied with the resulting variable binding, it may ask for an alternative solution (= binding of the variables), causing Prolog to reject the previously chosen clause and try the next one.

binding [of a variable]
Current value of the variable. See also backtracking and query.

built-in [predicate]
Predicate that is part of the Prolog system. Built in predicates cannot be redefined by the user, unless this is overruled using redefine_system_predicate/1.

body
Part of a clause behind the neck operator (:-).

clause
‘Sentence’ of a Prolog program. A clause consists of a head and body separated by the neck operator (:-) or it is a fact. For example:

parent(X) :-
    father(X, _).
Expressed “X is a parent if X is a father of someone”. See also variable and predicate.

**compile**
Process where a Prolog program is translated to a sequence of instructions. See also interpreted. SWI-Prolog always compiles your program before executing it.

**compound [term]**
Also called structure. It consists of a name followed by N arguments, each of which are terms. N is called the arity of the term.

**context module**
If a term is referring to a predicate in a module, the context module is used to find the target module. The context module of a goal is the module in which the predicate is defined, unless this predicate is module transparent, in which case the context module is inherited from the parent goal. See also module_transparent/1.

**dynamic [predicate]**
A dynamic predicate is a predicate to which clauses may be asserted and from which clauses may be retracted while the program is running. See also update view.

**exported [predicate]**
A predicate is said to be exported from a module if it appears in the public list. This implies that the predicate can be imported into another module to make it visible there. See also use_module/[1,2].

**fact**
Clause without a body. This is called a fact because interpreted as logic, there is no condition to be satisfied. The example below states john is a person.

```
person(john).
```

**fail**
A goal is said to have failed if it could not be proven.

**float**
Computers crippled representation of a real number. Represented as ‘IEEE double’.

**foreign**
Computer code expressed in other languages than Prolog. SWI-Prolog can only cooperate directly with the C and C++ computer languages.

**functor**
Combination of name and arity of a compound term. The term foo(a, b, c) is said to be a term belonging to the functor foo/3. foo/0 is used to refer to the atom foo.

**goal**
Question stated to the Prolog engine. A goal is either an atom or a compound term. A goal succeeds, in which case the variables in the compound terms have a binding or fails if Prolog fails to prove the goal.
hashing

Indexing technique used for quick lookup.

head

Part of a clause before the neck instruction. This is an atom or compound term.

imported [predicate]

A predicate is said to be imported into a module if it is defined in another module and made available in this module. See also chapter 5.

indexing

Indexing is a technique used to quickly select candidate clauses of a predicate for a specific goal. In most Prolog systems, including SWI-Prolog, indexing is done on the first argument of the head. If this argument is instantiated to an atom, integer, float or compound term with functor, hashing is used quickly select all clauses of which the first argument may unify with the first argument of the goal.

integer

Whole number. On all implementations of SWI-Prolog integers are at least 64-bit signed values. When linked to the GNU GMP library, integer arithmetic is unbounded. See also current prolog flag/2, flags bounded, max integer and min integer.

interpreted

As opposed to compiled, interpreted means the Prolog system attempts to prove a goal by directly reading the clauses rather than executing instructions from an (abstract) instruction set that is not or only indirectly related to Prolog.

meta-predicate

A predicate that reasons about other predicates, either by calling them, (re)defining them or querying properties.

module

Collection of predicates. Each module defines a name-space for predicates. built-in predicates are accessible from all modules. Predicates can be published (exported) and imported to make their definition available to other modules.

module transparent [predicate]

A predicate that does not change the context module. Sometimes also called a meta-predicate.

multifile [predicate]

Predicate for which the definition is distributed over multiple source-files. See multifile/1.

neck

Operator (:-) separating head from body in a clause.

operator

Symbol (atom) that may be placed before its operand (prefix), after its operand (postfix) or between its two operands (infix).

In Prolog, the expression a+b is exactly the same as the canonical term + (a, b).
operand
   Argument of an operator.

precedence
   The priority of an operator. Operator precedence is used to interpret \( a + b \times c \) as \( + (a, \times (b, c)) \).

predicate
   Collection of clauses with the same functor (name/arity). If a goal is proved, the system looks for a predicate with the same functor, then uses indexing to select candidate clauses and then tries these clauses one-by-one. See also backtracking.

predicate indicator
   Term of the form Name/Arity (traditional) or Name//Arity (ISO DCG proposal) where Name is an atom an Arity a non-negative integer. It acts as an indicator (or reference) to a predicate or DCG rule.

priority
   In the context of operators a synonym for precedence.

program
   Collection of predicates.

property
   Attribute of an object. SWI-Prolog defines various \_property predicates to query the status of predicates, clauses. etc.

prove
   Process where Prolog attempts to prove a query using the available predicates.

public list
   List of predicates exported from a module.

query
   See goal.

retract
   Remove a clause from a predicate. See also dynamic, update view and assert.

shared
   Two variables are called shared after they are unified. This implies if either of them is bound, the other is bound to the same value:

   \[
   \text{?- } A = B, \ A = a.\\
   A = a, \\
   B = a
   \]
singleton [variable]
  Variable appearing only one time in a clause. SWI-Prolog normally warns for this to avoid you making spelling mistakes. If a variable appears on purpose only once in a clause, write it as _ (see anonymous). Rules for naming a variable and avoiding a warning are given in section 2.15.1.

solution
  Bindings resulting from a successfully proven goal.

structure
  Synonym for compound term.

string
  Used for the following representations of text: a packed array (see section 4.23), SWI-Prolog specific), a list of character codes or a list of one-character atoms.

succeed
  A goal is said to have succeeded if it has been proven.

term
  Value in Prolog. A term is either a variable, atom, integer, float or compound term. In addition, SWI-Prolog also defines the type string

transparent
  See module transparent.

unify
  Prolog process to make two terms equal by assigning variables in one term to values at the corresponding location of the other term. For example:

  ?- foo(a, B) = foo(A, b).

  A = a,
  B = b

  Unlike assignment (which does not exist in Prolog), unification is not directed.

update view
  How Prolog behaves when a dynamic predicate is changed while it is running. There are two models. In most older Prolog systems the change becomes immediately visible to the goal, in modern systems including SWI-Prolog, the running goal is not affected. Only new goals ‘see’ the new definition.

variable
  A Prolog variable is a value that ‘is not yet bound’. After binding a variable, it cannot be modified. Backtracking to a point in the execution before the variable was bound will turn it back into a variable:
?- A = b, A = c.
No
?- (A = b; true; A = c).
A = b ;
A = _G283 ;
A = c ;
No

See also unify.
SWI-Prolog License Conditions and Tools

SWI-Prolog licensing aims at a large audience, combining ideas from the Free Software Foundation and the less principal Open Source Initiative. The license aims at:

- Make SWI-Prolog itself and its libraries are ‘As free as possible’.
- Allow for easy integration of contributions. See section E.2.
- Free software can build on SWI-Prolog without limitations.
- Non-free (open or proprietary) software can be produced using SWI-Prolog, although contributed pure GPL-ed components cannot be used.

To achieve this, different parts of the system have different licenses. SWI-Prolog programs consists of a mixture of ‘native’ code (source compiled to machine instructions) and ‘virtual machine’ code (Prolog source compiled to SWI-Prolog virtual machine instructions, covering both compiled SWI-Prolog libraries and your compiled application).

For maximal coherence between free licenses, we start with the two prime licenses from the Free Software Foundation, the GNU General Public License (GPL) and the Lesser GNU General Public License (LGPL), after which we add a proven (used by the GNU-C compiler runtime library as well as the GNU ClassPath project) exception to deal with the specific nature of compiled virtual machine code in a saved state.

E.1 The SWI-Prolog kernel and foreign libraries

The SWI-Prolog kernel and our foreign libraries are distributed under the LGPL. A Prolog executable consists of the combination of these ‘native’ code components and Prolog virtual machine code. The SWI-Prolog plrc utility allows for disassembling and re-assembling these parts, a process satisfying article 6b of the LGPL.

Under the LGPL SWI-Prolog can be linked to code distributed under arbitrary licenses, provided a number of requirements are fulfilled. The most important requirement is that, if an application replies on a modified version of SWI-Prolog, the modified sources must be made available.

E.1.1 The SWI-Prolog Prolog libraries

Lacking a satisfactory technical solution to handle article 6 of the LGPL, this license cannot be used for the Prolog source code that is part of the SWI-Prolog system (both libraries and kernel code). This situation is comparable to libgcc, the runtime library used with the GNU C-compiler. Therefore, we use the same proven license terms as this library. The libgcc license is the with a special exception. Below we rephrased this exception adjusted to our needs:
As a special exception, if you link this library with other files, compiled with a Free
Software compiler, to produce an executable, this library does not by itself cause the
resulting executable to be covered by the GNU General Public License. This exception
does not however invalidate any other reasons why the executable file might be covered
by the GNU General Public License.

E.2 Contributing to the SWI-Prolog project

To achieve maximal coherence using SWI-Prolog for Free and Non-Free software we advice the use
of the LGPL for contributed foreign code and the use of the GPL with SWI-Prolog exception for
Prolog code for contributed modules.

As a rule of thumb it is advised to use the above licenses whenever possible and only use a strict
GPL compliant license only if the module contains other code under strict GPL compliant licenses.

E.3 Software support to keep track of license conditions

Given the above, it is possible that SWI-Prolog packages and extensions will rely on the GPL.\(^1\) The
predicates below allow for registering license requirements for Prolog files and foreign modules. The
predicate eval_license/0 reports which components from the currently configured system are dis-
tributed under copy-left and open source enforcing licenses (the GPL) and therefore must be replaced
before distributing linked applications under non-free license conditions.

\begin{verbatim}
eval_license
\end{verbatim}

Evaluate the license conditions of all loaded components. If the system contains one or more
components that are licenced under GPL-like restrictions the system indicates this program
may only be distributed under the \texttt{GPL} license as well as which components prohibit the use of
other license conditions.

\begin{verbatim}
license(+LicenseId, +Component)
\end{verbatim}

Register the fact that \texttt{Component} is distributed under a license identified by \texttt{LicenseId}. The
most important \texttt{LicenseId}"s are:

\begin{verbatim}
swipl
\end{verbatim}

Indicates this module is distributed under the GNU General Public License (GPL) with
the SWI-Prolog exception:\(^2\)

\begin{quote}
As a special exception, if you link this library with other files, compiled with
SWI-Prolog, to produce an executable, this library does not by itself cause the
resulting executable to be covered by the GNU General Public License. This
exception does not however invalidate any other reasons why the executable file
might be covered by the GNU General Public License.
\end{quote}

---

\(^1\)On the Unix version, the default toplevel uses the GNU readline library for command-line editing. This library is
distributed under the GPL. In practice this problem is small as most final applications have Prolog embedded, without direct
access to the commandline and therefore without need for \texttt{libreadline}.

\(^2\)This exception is a straight re-phrasing of the license used for \texttt{libgcc}, the GNU-C runtime library facing similar
technical issues.
This should be the default for software contributed to the SWI-Prolog project as it allows the community to prosper both in the free and non-free world. Still, people using SWI-Prolog to create non-free applications must contribute sources to improvements they make to the community.

**lgpl**

This is the default license for foreign-libraries linked with SWI-Prolog. Use `PL_license()` to register the condition from foreign code.

**gpl**

Indicates this module is strictly Free Software, which implies it cannot be used together with any module that is incompatible to the GPL. Please only use these conditions when forced by other code used in the component.

Other licenses known to the system are `guile`, `gnu_ada`, `x11`, `expat`, `sml`, `public_domain`, `cryptix`, `bsd`, `zlib`, `constlgpl_compatible` and `gpl_compatible`. New licenses can be defined by adding clauses for the multifile predicate `license:license/3`. Below is an example. The second argument is either `gpl` or `lgpl` to indicate compatibility to these licenses. Other values cause the license to interpreted as *proprietary*. Proprietary licenses are reported by `eval_license/0`. See the file `boot/license.pl` for details.

```prolog
:- multifile license:license/3.

license:license(mylicense, lgpl,
    [ comment('My personal license'),
      url('http://www.mine.org/license.html')
    ]).

:- license(mylicense).
```

**license(+LicenseId)**

Intended as a directive in Prolog source files. It takes the current filename and calls `license/2`.

**void PL_license(const char *LicenseId, const char *Component)**

Intended for the install() procedure of foreign libraries. This call can be made before `PL_initialise()`.
E.4 Library predicates

E.4.1 aggregate

aggregate/3 Aggregate bindings in Goal according to Template.
aggregate/4 Aggregate bindings in Goal according to Template.
aggregate_all/3 Aggregate bindings in Goal according to Template.
aggregate_all/4 Aggregate bindings in Goal according to Template.
foreach/2 True if the conjunction of instances of Goal using the bindings from Generator is true.
free_variables/4 In order to handle variables properly, we have to find all the universally quantified variables in the Generator.

E.4.2 apply

exclude/3 Filter elements for which Goal fails.
include/3 Filter elements for which Goal succeed.
partition/4 Filter elements of List according to Pred.
partition/5 Filter list according to Pred in three sets.

E.4.3 assoc

assoc_to_list/2 Translate assoc into a pairs list
assoc_to_keys/2 Translate assoc into a key list
assoc_to_values/2 Translate assoc into a value list
empty_assoc/1 Test/create an empty assoc
gen_assoc/3 Non-deterministic enumeration of assoc
get_assoc/3 Get associated value
get_assoc/5 Get and replace associated value
list_to_assoc/2 Translate pair list to assoc
map_assoc/2 Test assoc values
map_assoc/3 Map assoc values
max_assoc/3 Max key-value of an assoc
min_assoc/3 Min key-value of an assoc
ord_list_to_assoc/3 Translate ordered list into an assoc
put_assoc/4 Add association to an assoc

E.4.4 broadcast

broadcast/1 Send event notification
broadcast_request/1 Request all agents
listen/2 Listen to event notifications
listen/3 Listen to event notifications
unlisten/1 Stop listening to event notifications
unlisten/2 Stop listening to event notifications
unlisten/3 Stop listening to event notifications
listening/3 Who is listening to event notifications?
E.4. LIBRARY PREDICATES

E.4.5 check

check/0 Program completeness and consistency
list_undefined/0 List undefined predicates
list_auto_load/0 List predicates that require autoload
list_redefined/0 List locally redefined predicates

E.4.6 lists

append/2 Concatenate a list of lists
append/3 Concatenate lists
delete/3 Delete all matching members from a list
flatten/2 Transform nested list into flat list
intersection/3 Set intersection
is_set/1 Type check for a set
list_to_set/2 Remove duplicates
max_list/2 Largest number in a list
member/2 Element is member of a list
min_list/2 Smallest number in a list
nextto/3 Y follows X in List
nth0/3 N-th element of a list (0-based)
nth1/3 N-th element of a list (1-based)
numlist/3 Create list of integers in interval
permutation/2 Test/generate permutations of a list
reverse/2 Inverse the order of the elements in a list
select/3 Select element of a list
selectchk/3 Semi-deterministic selection from a list
subset/2 Check subset relation for unordered sets
subtract/3 Delete elements that do not satisfy condition
sumlist/2 Add all numbers in a list
union/3 Union of two sets

E.4.7 option

merge_options/3 Merge two option lists.
meta_options/3 Perform meta-expansion on options that are module-sensitive.
option/2 Get an option from a OptionList.
option/3 Get an option from a OptionList.
select_option/3 Get and remove option from an option list.
select_option/4 Get and remove option with default value.

E.4.8 ordsets

ord_empty/1 Test empty ordered set
list_to_ord_set/2 Create ordered set
ord_add_element/3 Add element to ordered set
ord_del_element/3 Delete element from ordered set
ord_intersect/2 Test non-empty intersection
ord_intersection/3 Compute intersection
ord_disjoint/2 Test empty intersection
ord_subtract/3 Delete set from set
ord_union/3 Union of two ordered sets
ord_union/4 Union and difference of two ordered sets
ord_subset/2 Test subset
ord_memberchk/2 Deterministically test membership

E.4.9 prologxref

prolog:called_by/2 (hook) Extend cross-referencer
xrefBuilt_in/1 Examine defined built-ins
xref_called/3 Examine called predicates
xref_clean/1 Remove analysis of source
xref_current_source/1 Examine cross-referenced sources
xref_defined/3 Examine defined predicates
xref_exported/2 Examine exported predicates
xref_module/2 Module defined by source
xref_source/1 Cross-reference analysis of source

E.4.10 pairs

group_pairs_by_key/2 Group values with the same key.
map_list_to_pairs/3 Create a key-value list by mapping each element of List.
pairs_keys/2 Remove the values from a list of Key-Value pairs.
pairs_keys_values/3 True if Keys holds the keys of Pairs and Values the values.
pairs_values/2 Remove the keys from a list of Key-Value pairs.
transpose_pairs/2 Swap Key-Value to Value-Key and sort the result on Value (the new key) using keysort/2.

E.4.11 pio

pure_input

phrase_from_file/2 Process the content of File using the DCG rule Grammar.
phrase_from_file/3 As phrase_from_file/2, providing additional Options.
stream_to_lazy_list/2 Create a lazy list representing the character codes in Stream.

E.4.12 readutil

read_line_to_codes/2 Read line from a stream
read_line_to_codes/3 Read line from a stream
read_stream_to_codes/2 Read contents of stream
read_stream_to_codes/3 Read contents of stream
read_file_to_codes/3 Read contents of file
E.4. LIBRARY PREDICATES

read_file_to_terms/3  Read contents of file to Prolog terms

E.4.13 record

record/1  Define named fields in a term

E.4.14 registry

This library is only available on Windows systems.

registry_get_key/2  Get principal value of key
registry_get_key/3  Get associated value of key
registry_set_key/2  Set principal value of key
registry_set_key/3  Set associated value of key
registry_delete_key/1  Remove a key
shell_register_file_type/4  Register a file-type
shell_register_dde/6  Register DDE action
shell_register_prolog/1  Register Prolog

E.4.15 ugraphs

vertices_edges_to_ugraph/3  Create unweighted graph
vertices/2  Find vertices in graph
edges/2  Find edges in graph
add_vertices/3  Add vertices to graph
delete_vertices/3  Delete vertices from graph
add_edges/3  Add edges to graph
delete_edges/3  Delete edges from graph
transpose/2  Invert the direction of all edges
neighbors/3  Find neighbors of vertex
neighbours/3  Find neighbors of vertex
complement/2  Inverse presence of edges
compose/3
top_sort/2  Sort graph topologically
top_sort/3  Sort graph topologically
transitive_closure/2  Create transitive closure of graph
reachable/3  Find all reachable vertices
ugraph_union/3  Union of two graphs

E.4.16 url

file_name_to_url/2  Translate between a filename and a file:/ URL.
global_url/3  Translate a possibly relative URL into an absolute one.
http_location/2  Construct or analyze an HTTP location.
is_absolute_url/1  True if URL is an absolute URL.
parse_url/2  Construct or analyse a URL.
E.4.17 **www_browser**

```
www_open_url/1  Open a web-page in a browser
```

E.4.18 **clp/clp_distinct**

```
all_distinct/1  Demand distinct values
vars_in/2     Declare domain of variable as set
vars_in/3     Declare domain of variable as interval
```

E.4.19 **clp/clpfd**

```
# /
# /
# <
# <=
# <=>
# <=
# <=
# >
# >=
# !=
# |
# |
all_different/1 Vars are pairwise distinct.
all_distinct/1 Like all_different/1, with stronger propagation.
element/3     The N-th element of the list of integers Is is I.
fd_dom/2     Dom is the current domain (see in/2) of Var.
fd_inf/2     Inf is the infimum of the current domain of Var.
fd_size/2     Size is the number of elements of the current domain of Var, or the atom *sup* if the domain is unbounded.
fd_sup/2     Sup is the supremum of the current domain of Var.
fd_var/1     True iff Var is a CLP(FD) variable.
in/2         Var is an element of Domain.
indomain/1   Bind Var to all feasible values of its domain on backtracking.
ins/2        The variables in the list Vars are elements of Domain.
label/1      Equivalent to labeling([], Vars).
labeling/2    Labeling means systematically trying out values for the finite domain variables Vars until all of them are.
lex_chain/1   Lists are lexicographically non-decreasing.
serialized/2  Constrain a set of intervals to a non-overlapping sequence.
sum/3        The sum of elements of the list Vars is in relation Rel to Expr.
tuples_in/2   Relation must be a list of lists of integers.
zcompare/3    Analogous to compare/3, with finite domain variables A and B.
```
### E.4.20 clpqr

<table>
<thead>
<tr>
<th>Predicate</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>entailed/1</td>
<td>Check if constraint is entailed</td>
</tr>
<tr>
<td>inf/2</td>
